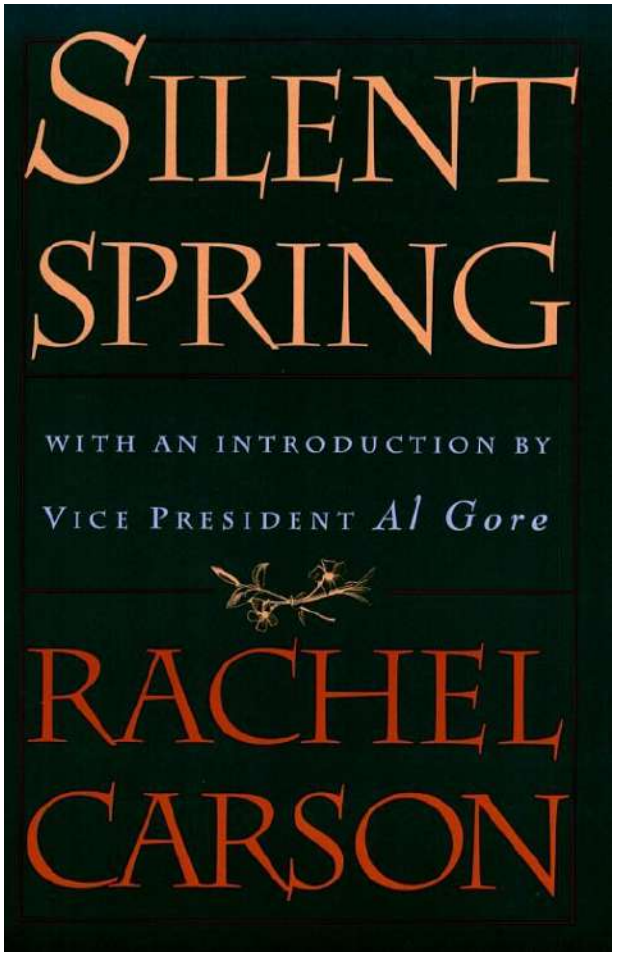
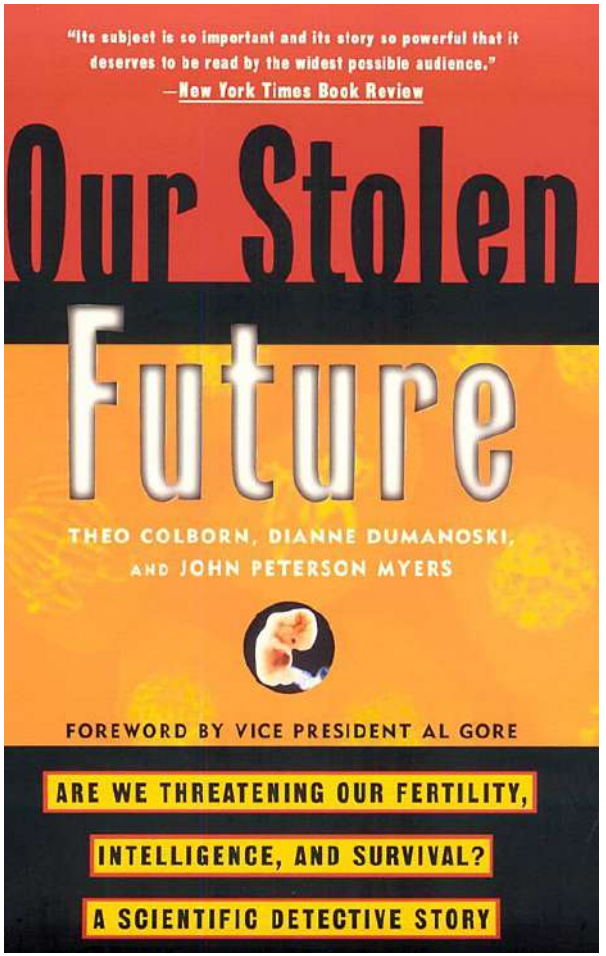
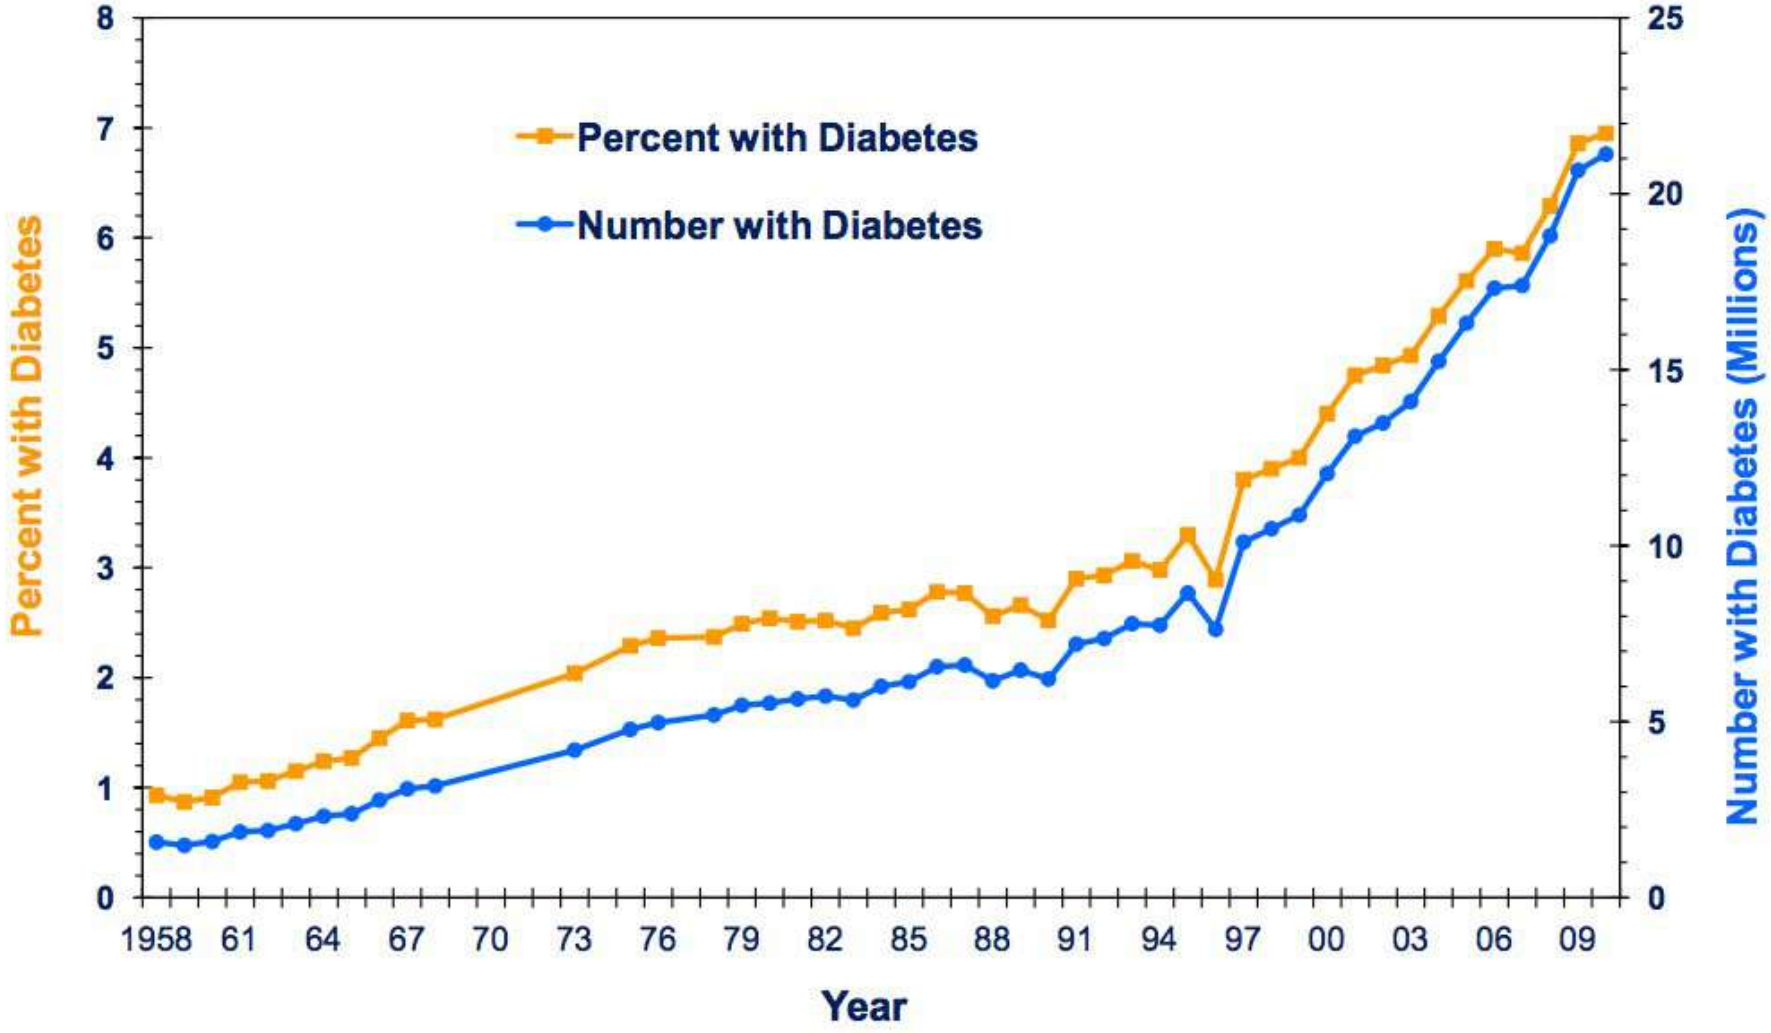
Silent Spring to Silent Sperm?

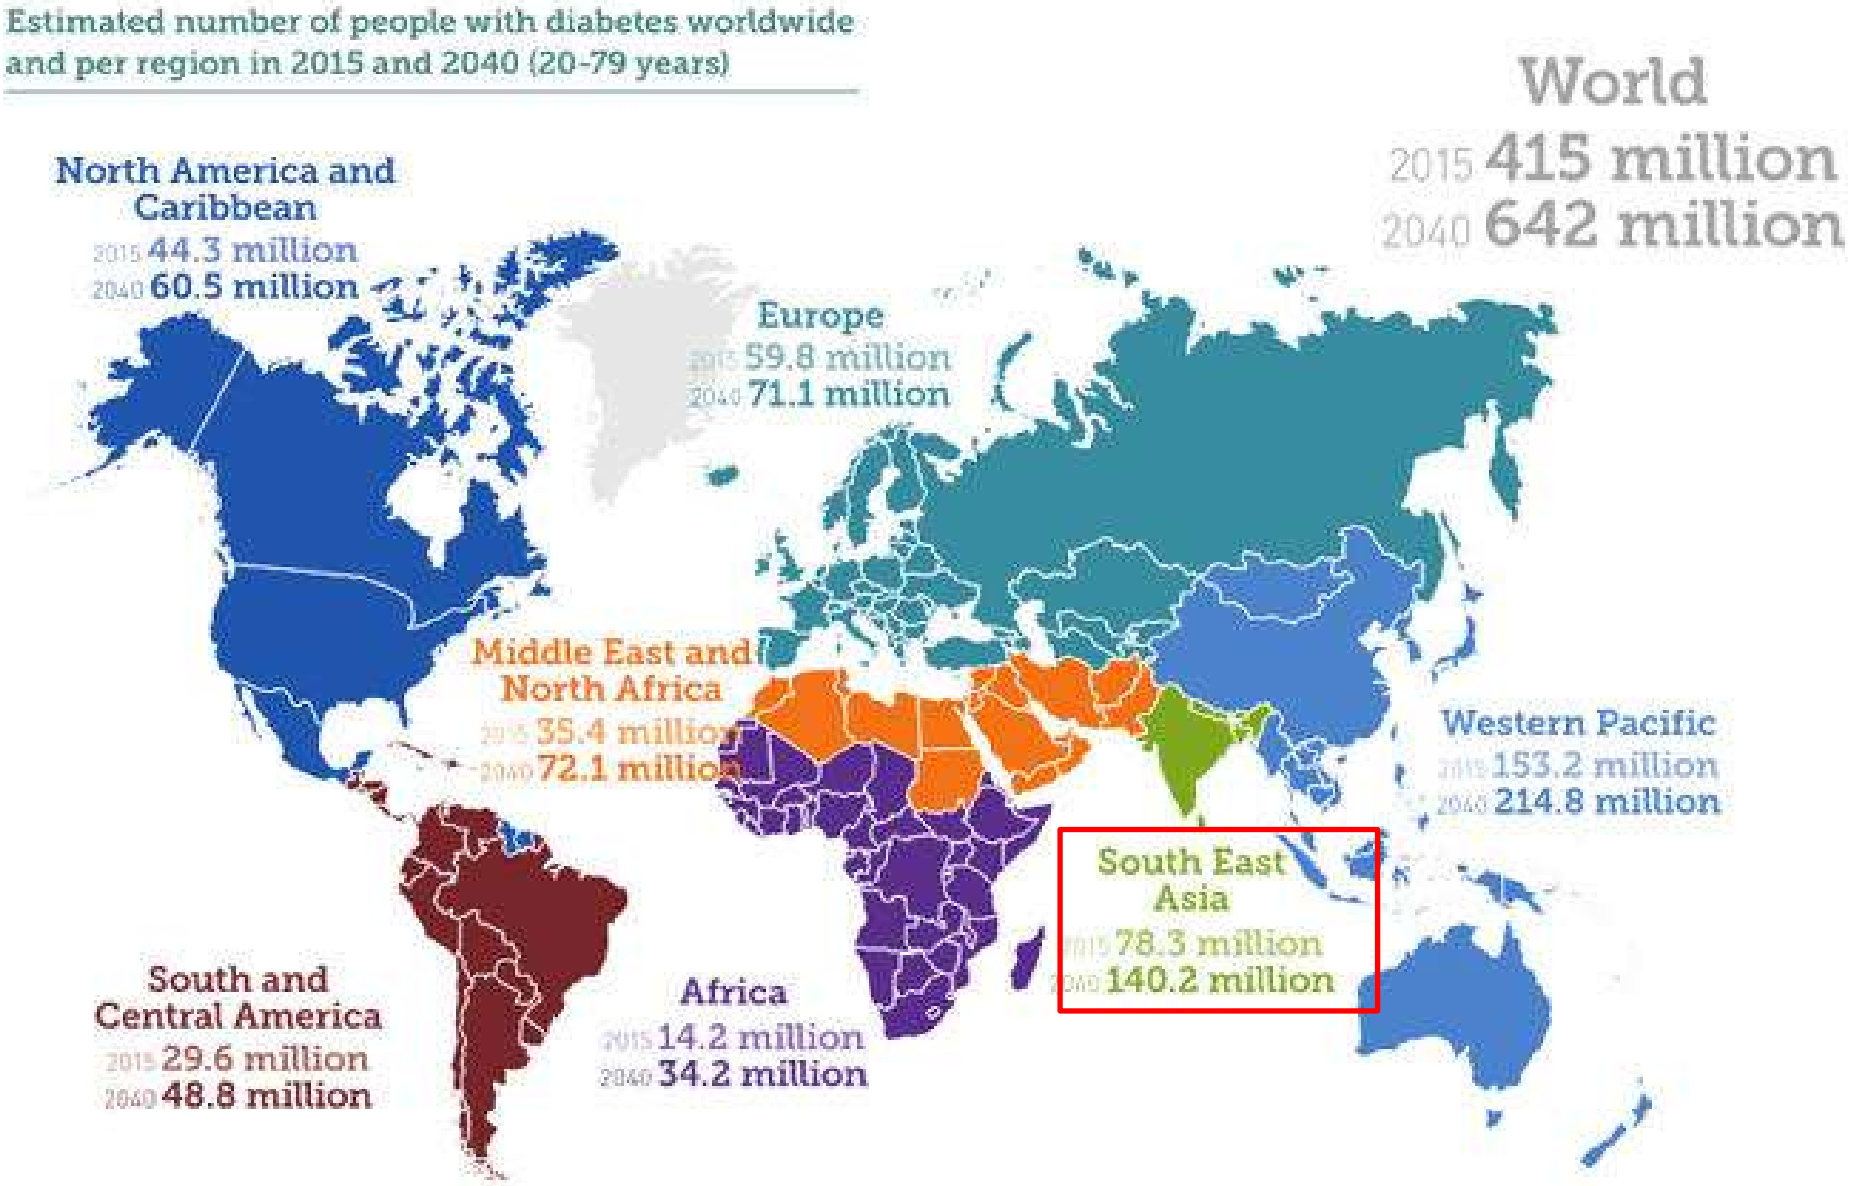




Number and Percentage of U.S. Population with Diagnosed Diabetes, 1958-2010



Numbers of Type 2 Diabetes



Future Research Questions:

1. What is the overall health burden of these chemicals with long-term, cumulative exposure over a life-time, versus short-term use?
2. What proportion of susceptibility to obesity is explained by chemicals in the environment

American Heart Association | American Stroke Association

Policy Statement on Environmental Endocrine Disrupting Chemicals & the Impact on Obesity and Cardiovascular Disease

Position

2010 September

The American Heart Association (AHA) recognizes that the causes of obesity are multi-factorial and complex, and therefore, must be addressed on multiple levels. Recently, endocrine disrupting chemicals (EDCs) such as diethylstilbestrol, bisphenol A, phthalates and organotins have been proposed as potential "obesogens" that contribute to a toxic chemical burden that may initiate or exacerbate the development of obesity and its related comorbitites.[1-7] EDCs are found in a variety of products including plastics, cosmetics, shampoos, soaps, lubricants, pesticides, paints and flame-retardant materials.[2, 8] Laboratory studies are still elucidating the exact mechanisms by which these substances affect weight, but current evidence suggests that they disrupt developmental and homeostatic controls over fat production and energy balance.[9-12] However, determining the link with obesity can be especially challenging because obese people might be eating more and therefore exposing themselves to more of the chemicals in food packaging. Teasing out causality can be challenging. Although limited research exists on the effect of these environmental chemicals on human populations, several epidemiological studies have found that chemical exposure, particularly during critical developmental periods, is positively correlated with increased weight, cardiovascular disease and diabetes.[8, 13-18] Additional research is needed to clarify these results and establish a causal link between exposure to EDCs and adverse health effects in humans as well as discern the physiological/cellular/metabolic impact of exposure. The AHA recommends further research before taking a proactive advocacy position.

Environmental Factors of Type 2 Diabetes

- Smoking
- Arsenic
- PCBs
- POPs
- Phthalates
- Bisphenol A

Environ Health Perspect 2012 Review

Figure 2. Association between arsenic and diabetes in areas of relatively high exposures (> 150 ppm drinking water).

PCBs and Diabetes Mellitus

Environ Health Perspect
2012 Review

Polychlorinated Biphenyls and Dibenzofurans 1978~1979

- About 2,000 **Yucheng** (oil-disease) victims were Taiwanese people exposed to **polychlorinated biphenyls (PCBs)** and their heat-degradation products, mainly polychlorinated dibenzofurans (**PCDFs**), from the ingestion of contaminated rice oil in 1978-79.
- OR of **5.5** for DM and **3.5** for hypertension for Yucheng women 24 years later

Increased Risk of Diabetes and Polychlorinated Biphenyls and Dioxins

A 24-year follow-up study of the Yucheng cohort

Wang SL and Kuo YL. *Diabetes Care* 31:1574–1579, 2008

RESULTS — The diabetes risk to members of the Yucheng cohort relative to their reference subjects was significantly increased for women (odds ratio [OR] 2.1 [95% CI 1.1–4.5]) but not for men after considering age, BMI, cigarette smoking, and alcohol intake. Yucheng women diagnosed with chloracne had adjusted ORs of 5.5 (95% CI 2.3–13.4) for diabetes and 3.5 (1.7–7.2) for hypertension compared with those who were chloracne free.

[g] Department of Environmental and Occupational Medicine, National Taiwan University College of Medicine and National Taiwan University Hospital, Taipei 100, Taiwan
[h] Department of Internal Medicine and Cardiovascular Center, National Taiwan University Hospital, Taipei 100, Taiwan

Conclusion: Higher serum concentrations of BPA were associated with increased CIMT in this cross-sectional study of adolescents and young adults. Studies to clarify the mechanisms of these associations are needed.

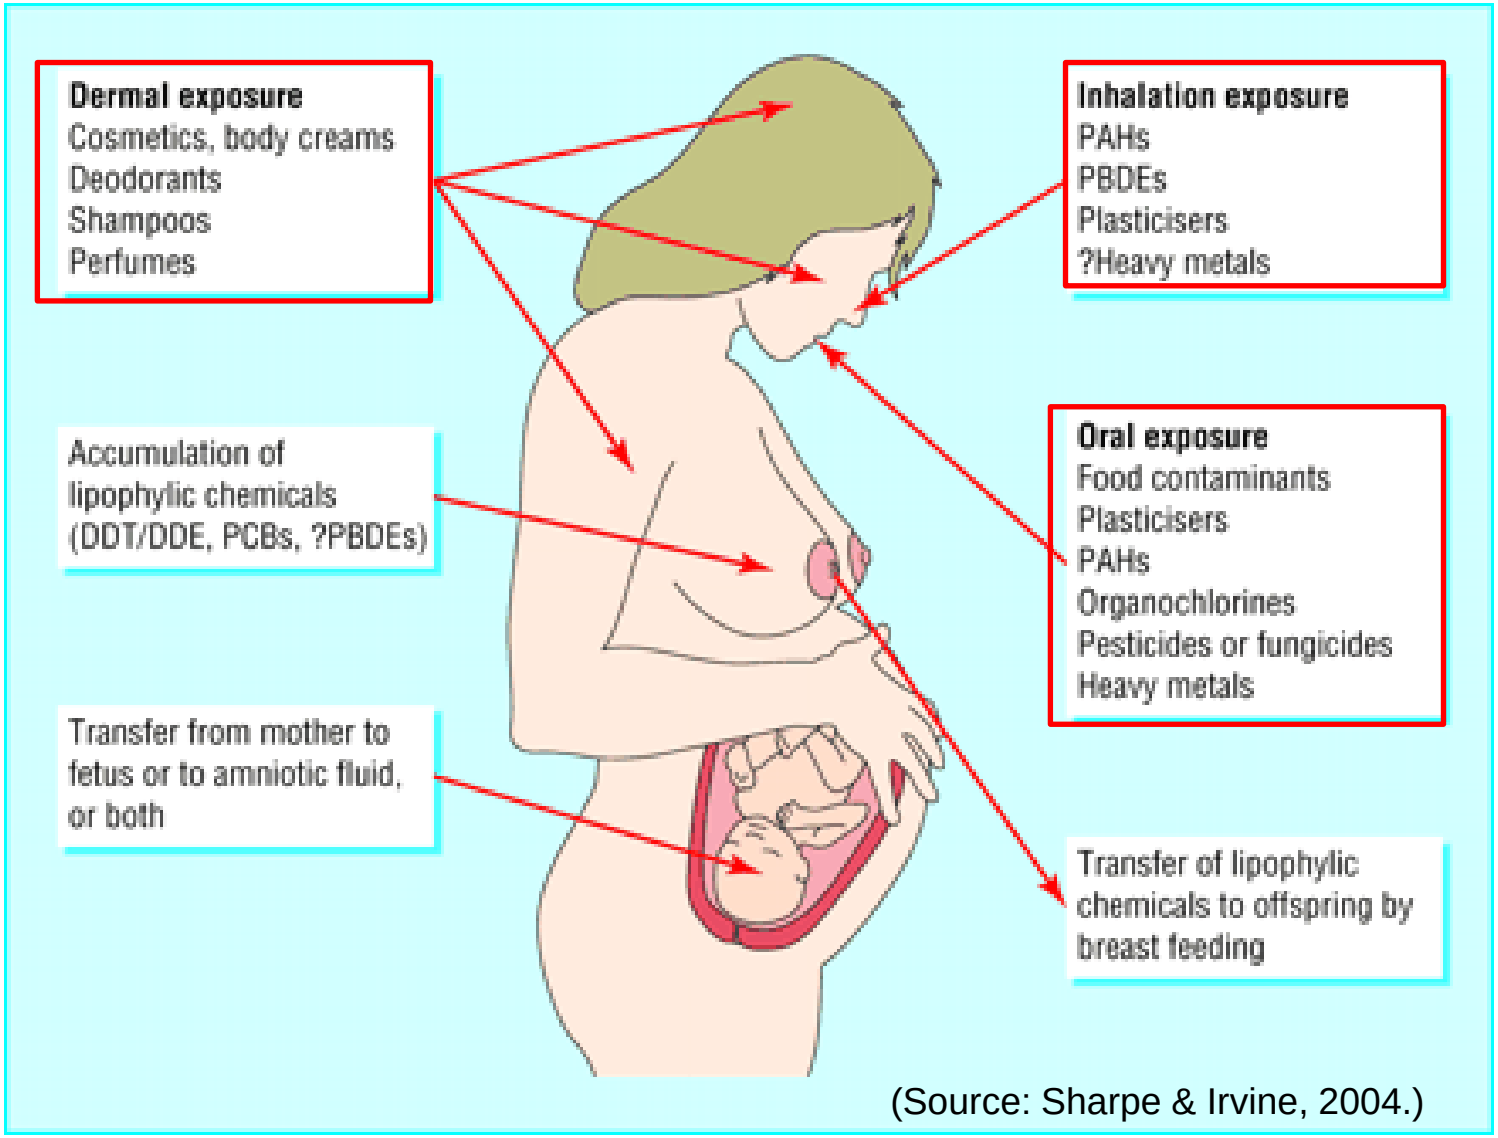
Environmental Exposures That Affect the Endocrine System

- **Pesticides** (insecticides such as o,p'-DDT, endosulfan, dieldrin, methoxychlor, kepone, dicofol, toxaphene, chlordane; herbicides such as alachlor, atrazine and nitrofen; fungicides such as benomyl, ferbam, and maneb; and fumigants such as aldicarb and dibromochloropropane)
- **Industrial chemicals** (polychlorinated biphenyls (PCBs), dioxin and benzo(a)pyrene)
- **Brominated flame retardants** (polybrominated diphenyl ethers, PBDEs)
- **Perfluoroalkylated substances**
- **Products associated with plastics (bisphenol A, phthalates)**
- **Ordinary household products** (breakdowns products of detergents and associated surfactants, including nonylphenol and octylphenol);
- **Pharmaceuticals** (drug estrogens - birth control pills, diethylstilbestrol (DES), cimetidine)
- **Heavy metals** (lead, mercury, arsenic , cadmium, and tin)

Persistent Organic Pollutants (POPs)

Routes of Human Exposure to Some Common Environmental Chemicals



(Source: Sharpe & Irvine, 2004.)

Phthalate Plasticizer Event in Taiwan 2011

A major incident of phthalate-contaminated foodstuffs happened in Taiwan between April and July, 2011. Phthalates were deliberately added to foodstuffs as a substitute of emulsifier (Clouding agent).

Wu et al. Environ Int. 2012 Sep;44:75-9. **The public health threat of phthalate-tainted foodstuffs in Taiwan: the policies the government implemented and the lessons we learned.**

What is Phthalates?

- Phthalates are **diesters of phthalic acids**, a class of industrial chemicals extensively used since the early 20th century as softeners of plastics, solvents in perfumes, and additives to hairsprays and lubricants and as insect repellents.
- Di-2-ethylhexyl phthalate (DEHP) is used primarily as a plasticizer for polyvinyl chloride (PVC) and can therefore be found in a variety of products such as **floor and wall coverings, vinyl gloves, toys, child care articles, food packaging materials, and medical devices** (Green et al. 2005).

Intake, absorption and excretion

- Intake via **food, food packaging and water, polluted dust**
- After absorption, the parent diester phthalates are rapidly hydrolyzed to the corresponding **monoesters**, some of which are then further metabolized, with the metabolites excreted in **urine and feces**. In humans, phthalates are eliminated mostly within hours, with **excretion complete by a day or two; half-lives in the body are in hours** (Koch and Calafat 2009).
- For phthalates with short alkyl chains, monoesters represent the major human metabolite, but in the case of phthalates with long alkyl chains, including **DEHP, diisononyl phthalate (DINP) and diisodecyl phthalate (DIDP)**, the monoesters are further metabolized via ω- and ω-1-oxidation of the aliphatic side chain (Agency for Toxic Substances and Disease Registry 2002).

Eating Phthaltes Everyday

Lifestyles and daily life

Selected metabolites of di[2-ethylhexyl) phthalate) (DEHP) in humans: mono(2-ethylhexyl) phthalate (MEHP), mono(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono(2-ethyl-5-oxohexyl) phthalate (MEOHP), and mono(2-ethyl-5-carboxypentyl) phthalate (MECPP).

Evidence of Phthalates Exposure and Cardiovascular Risk Factors

- A growing number of reports show that phthalates are associated with cardiovascular disease risk factors.
- Most studies are from the National Health and Nutrition Examination Survey (NHANES) data, with **increased risk** of
- Obesity and altered glucose homeostasis (Huang et al. 2014; Stahlhut et al. 2007; Trasande et al. 2013)
- Diabetes mellitus (James-Todd et al. 2012; Lind et al. 2012)
- Albuminuria (Trasande et al. 2014)
- Higher systolic blood pressure (Trasande et al. 2013)
- Inflammation markers including absolute neutrophil counts, alkaline phosphatase and ferritin levels (Ferguson et al. 2012), and CRP (Ferguson et al. 2011).

Positive association between concentration of phthalate metabolites in urine and microparticles in adolescents and young adults

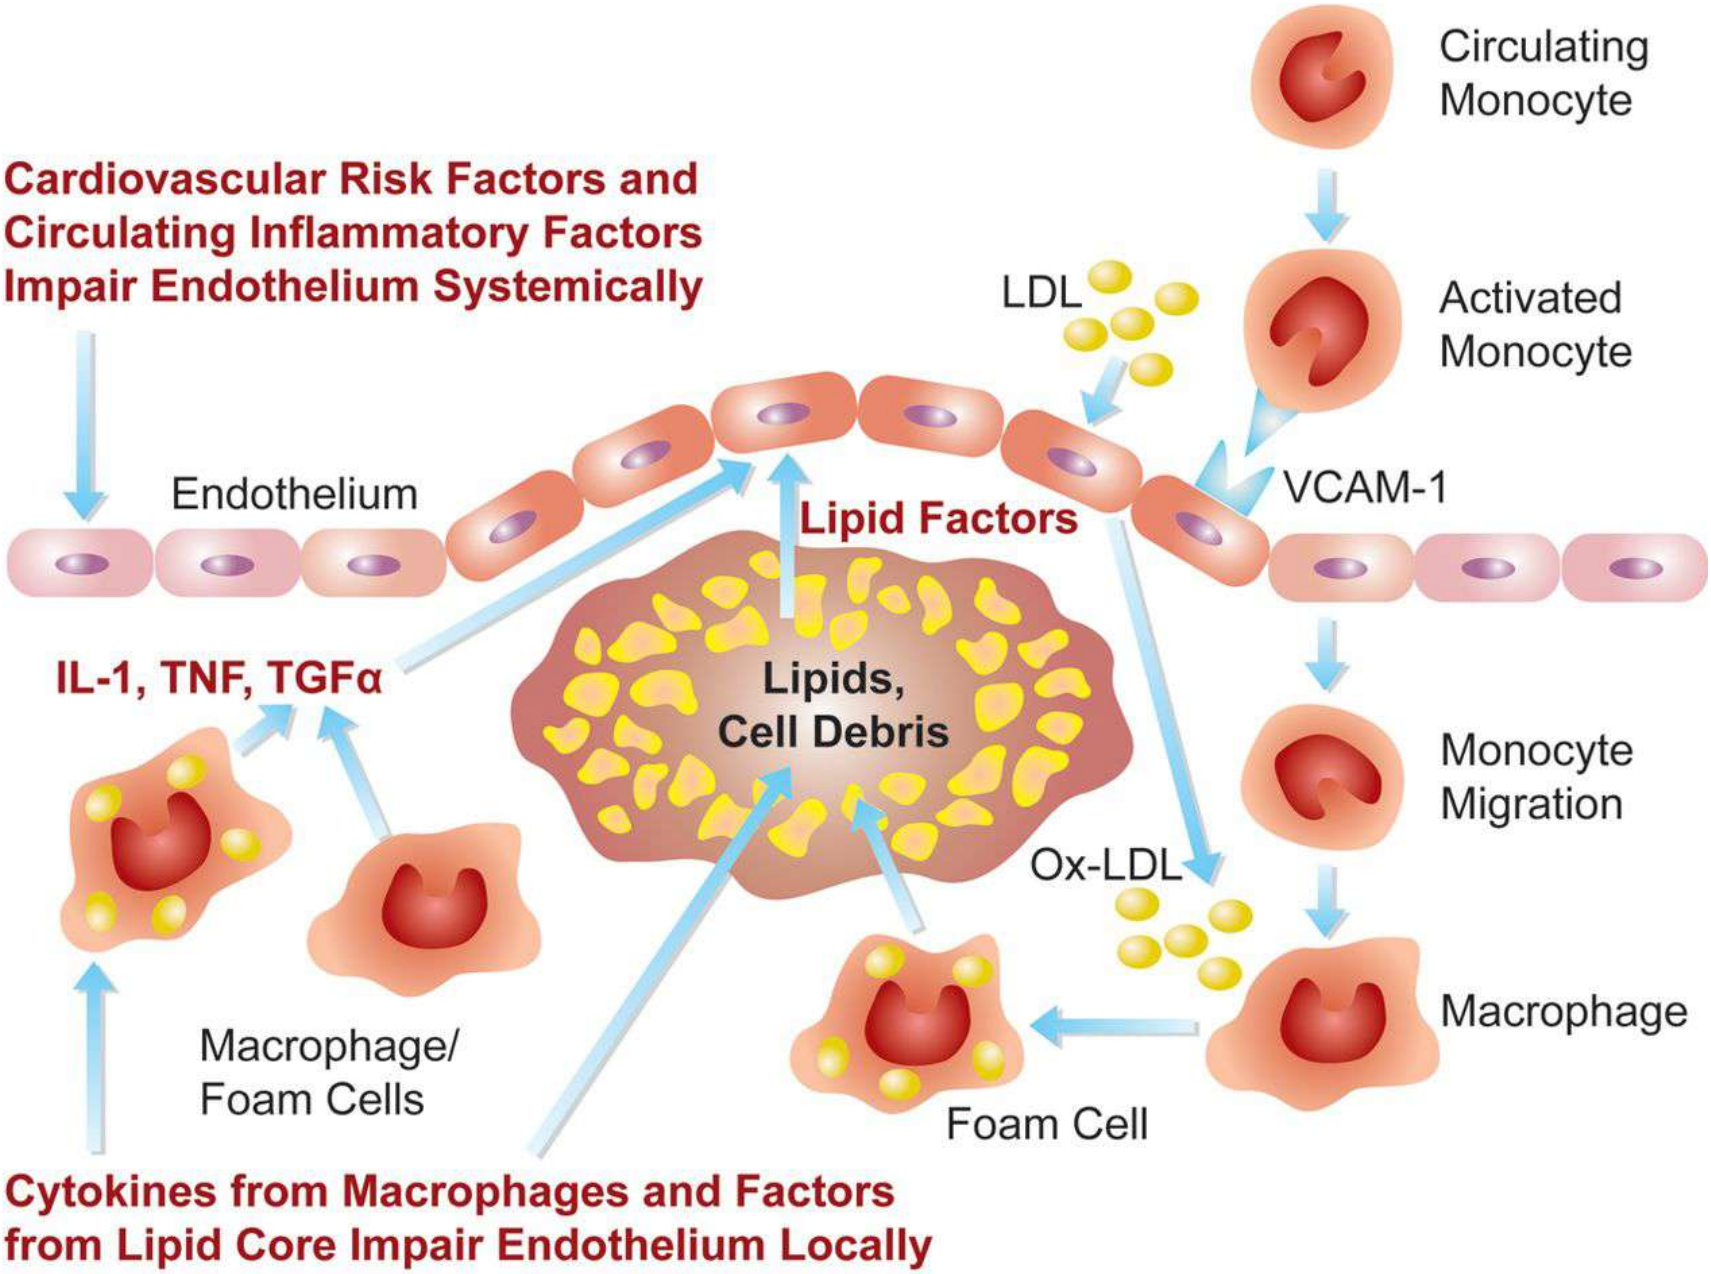
Chien-Yu Lin [a,b], Chia-Jung Hsieh [c], Shyh-Chyi Lo [d], Pau-Chung Chen [e,f,g,l], Pao-Ling Tomg [h,l], Anren Hu [i], Fung-Chang Sung [j], Ta-Chen Su [e,k,*]

- In this study, we test the possible associations between endothelial and platelet microparticles and phthalates exposure in adolescents and young adults.

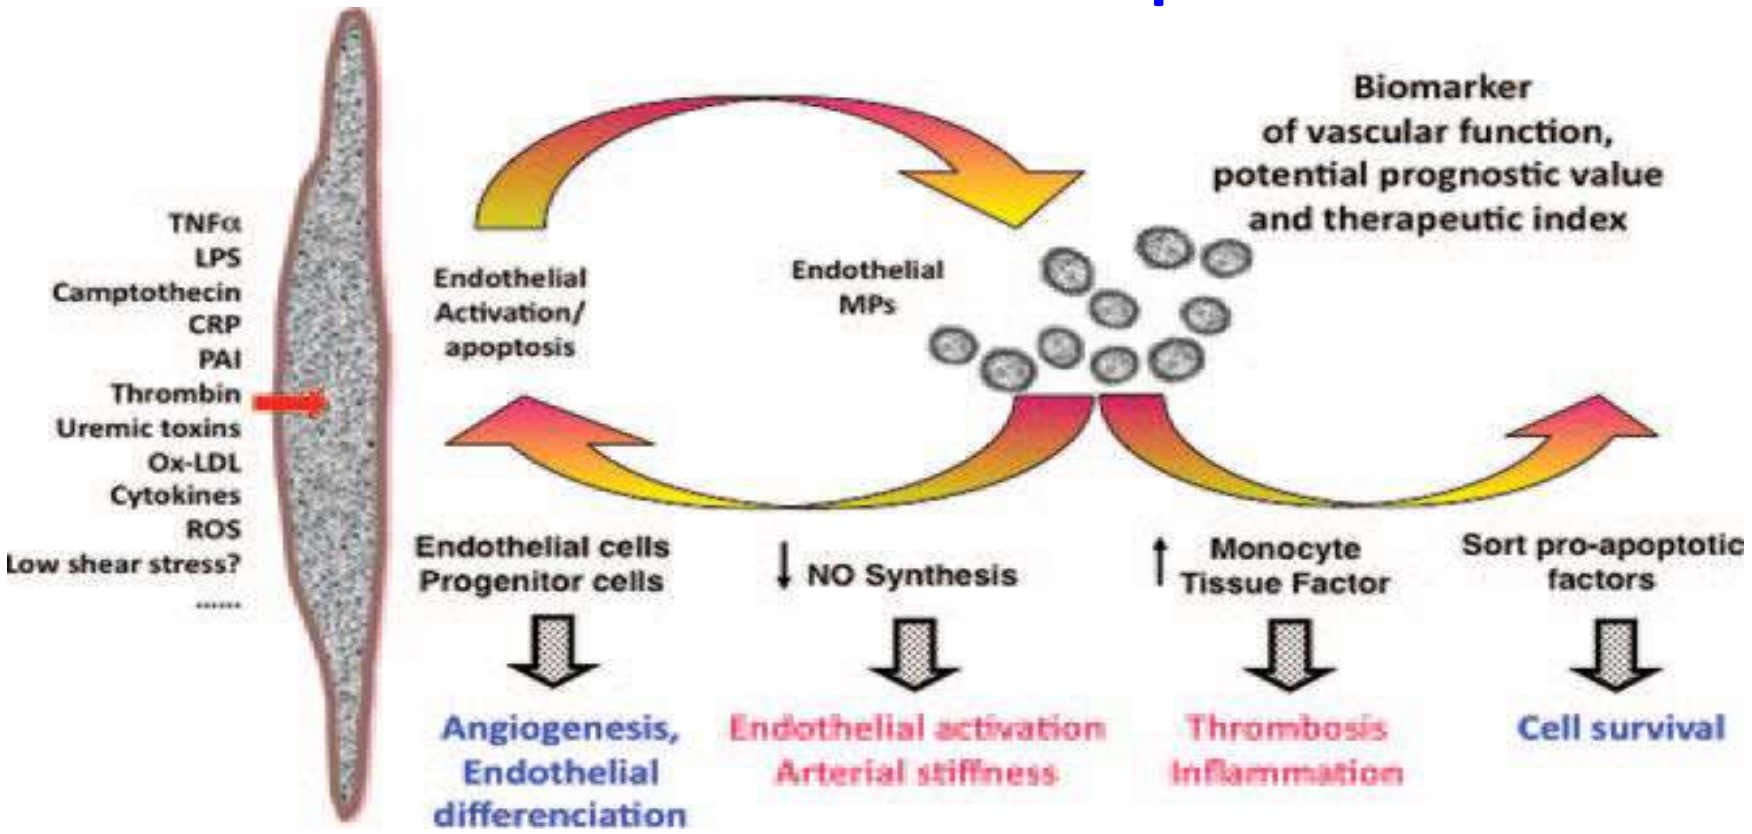
Microparticles and Atherosclerosis

- Atherosclerosis, which predisposes to CVD, is often accompanied by endothelial dysfunction and associated endothelium injury.
- Cell apoptosis, inflammatory activation occurring during atherosclerosis development **induce the formation of microparticles.**
- The attachment of monocytes to the endothelium, followed by their migration into the intima, is a crucial step in the development of atherosclerotic lesions (Lutterotti et al. 2006).
- Because CD31 was expressed on apoptotic platelet and endothelial cells and CD42a was expressed only on apoptotic platelet cells, CD31+/CD42a− was defined as a marker on **endothelial microparticles (EMPs)** that were shed from apoptotic endothelial cells (Dignat-George and Boulanger 2011)

Endothelial Dysfunction in Vulnerable Plaques



Endothelial microparticles



- Microparticles are small vesicles, between 0.1 and 1 µm in diameter.
- Microparticles concentrations are increased in patients with cardiovascular risk factors after cardiovascular events (Baron, 2012).
- **A recent study has focused on endothelial microparticles (EMPs) and platelet microparticles (PMPs) as emerging surrogate markers of chronic endothelial dysfunction (Werner et al. 2006).**

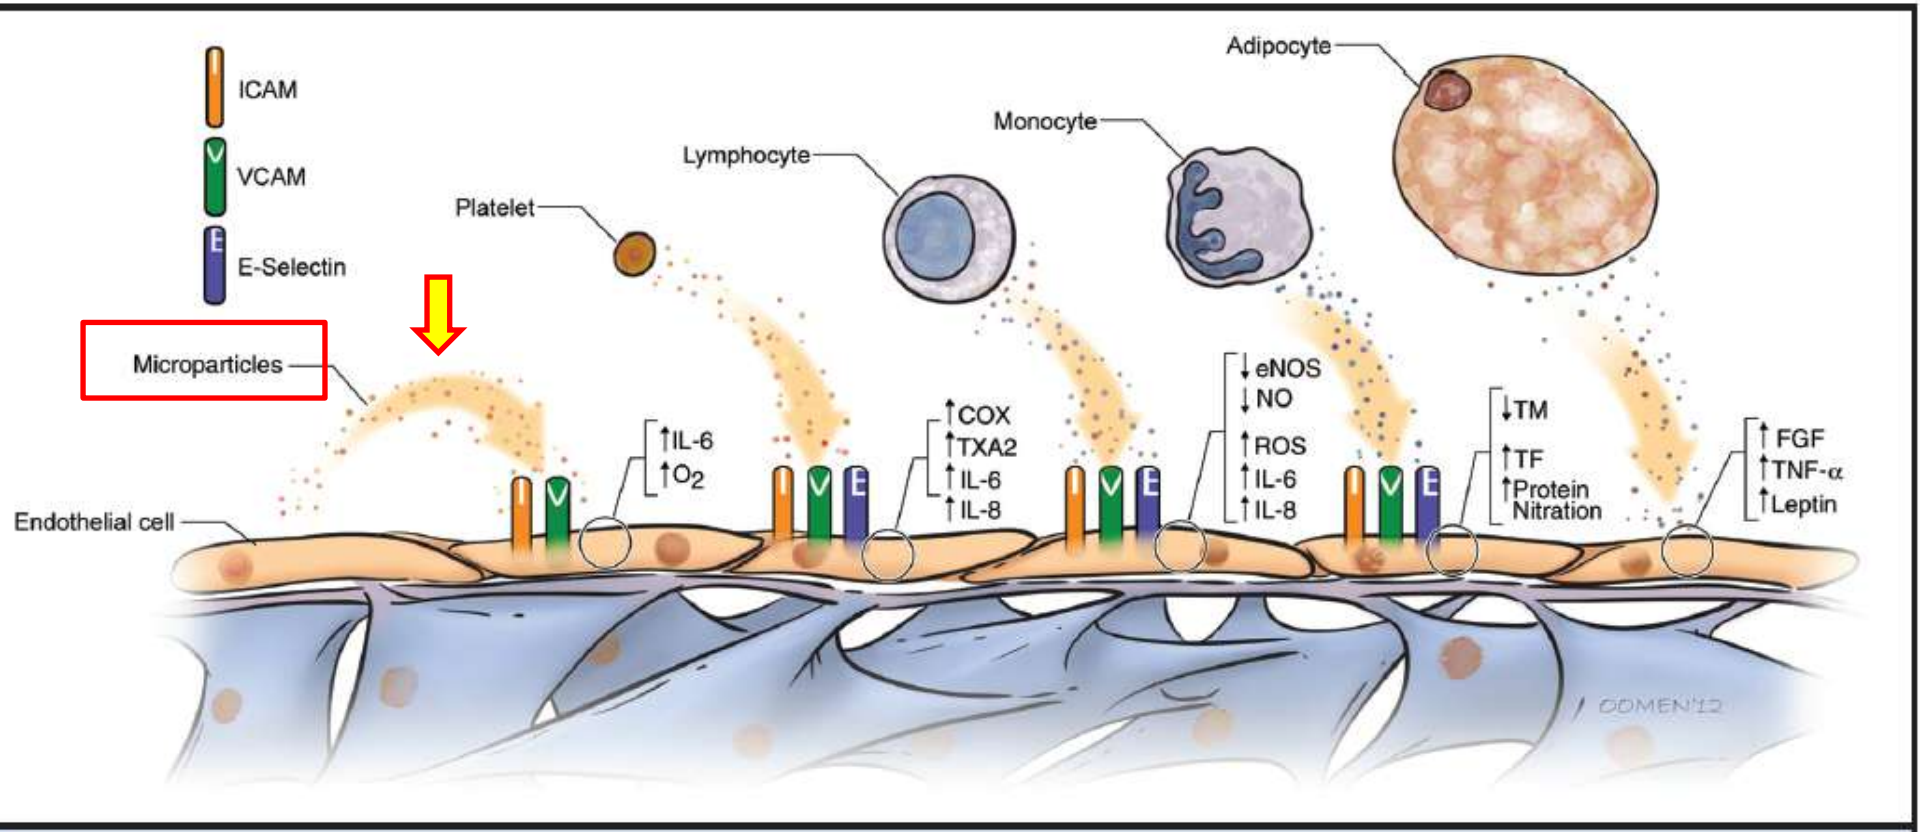


Fig. 1. Implication of circulating MPs on endothelial dysfunction.

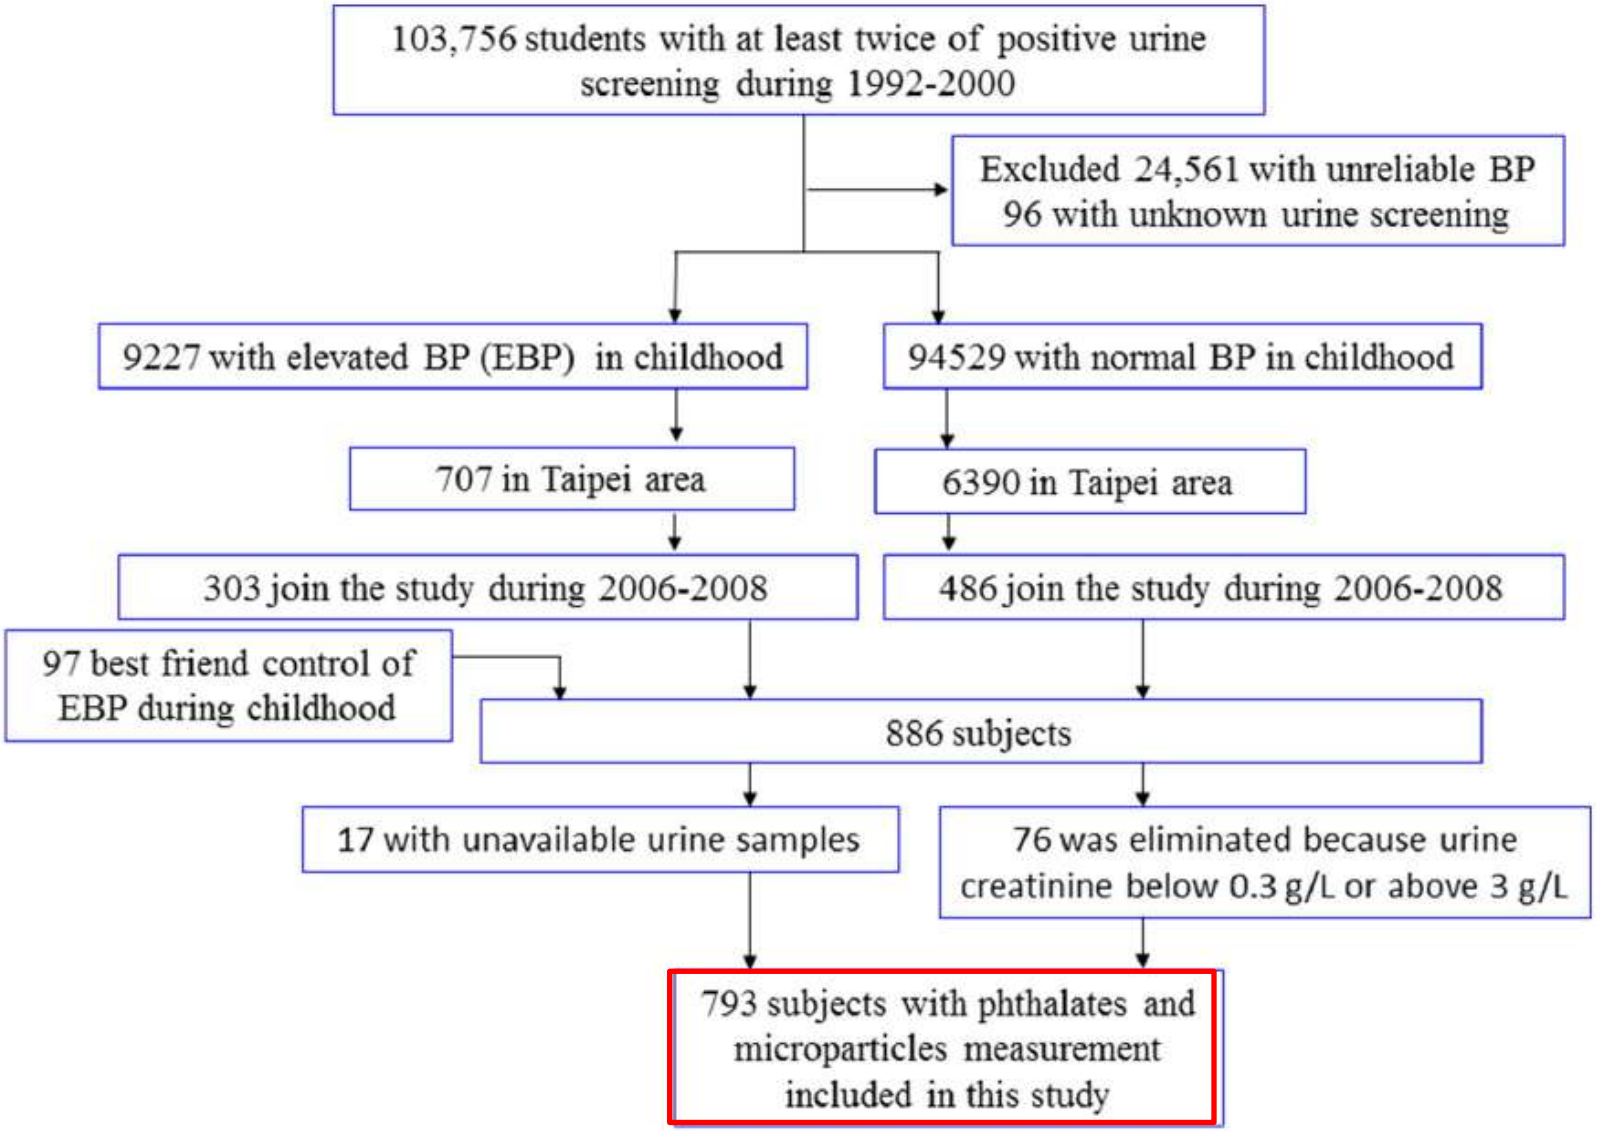
Microparticles elicit endothelial dysfunction by disrupting NO production, promoting inflammation and coagulation and altering angiogenesis and apoptosis. TXA2, thromboxane A2; TM, thrombomodulin. ©2012 Glen Oomen. Reproduced with permission.

Fina Lovren, Subodh Verma. Evolving Role of Microparticles in the Pathophysiology of Endothelial Dysfunction. Clin Chem 2013; 59:1166-74.

Methods

- **The endothelial microparticles (EMPs), platelet microparticles (PMPs) and CD14** were measured with a **flow cytometer method** (Chirinos et al. 2005).
- In brief, the microparticles were measured simultaneously in citrated serum by a pair of fluorescent monoclonal antibodies: phycoerythrin-labeled anti-CD31, fluorescein isothiocyanate-labeled anti CD42a and fluorescein isothiocyanate-labeled anti CD14 (BD bioscience). The values of the microparticles are reported as counts/µL.
- **Urinary metabolites of phthalates** were measured by standard method with **LC-MS/MS system**.



From 2006 to 2008 we established a cohort, the YOung TAiwanese Cohort (YOTA) Study, based on students with and without childhood EBP selected from the 1992-2000 mass urine screening population (Su, et al. JAT 2014 Nov.).

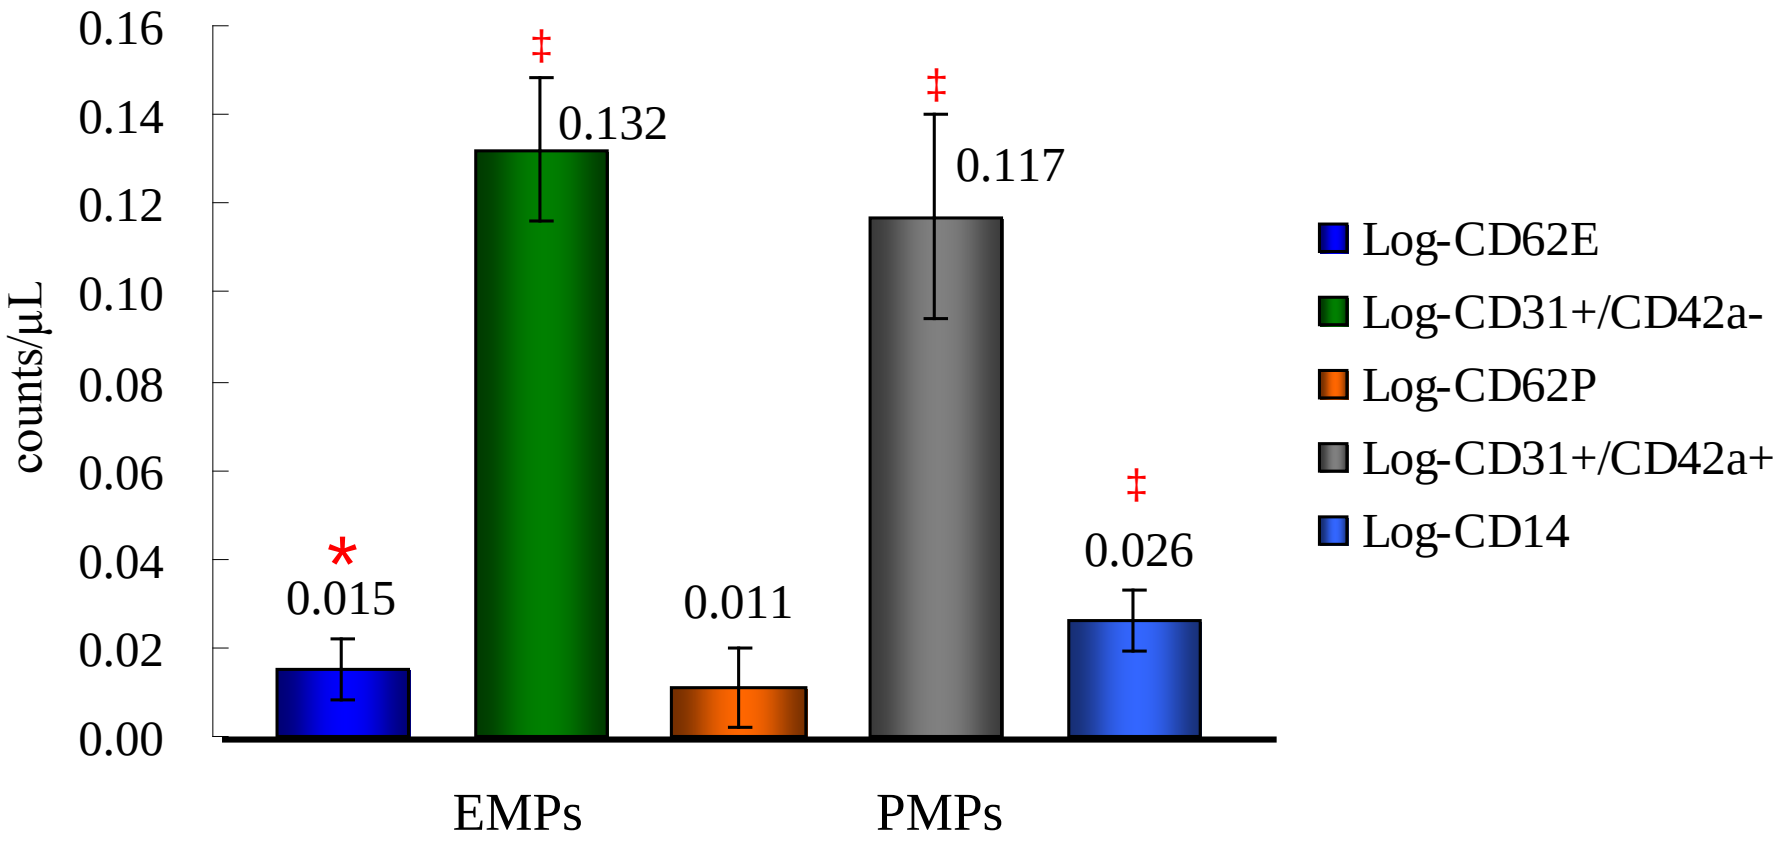
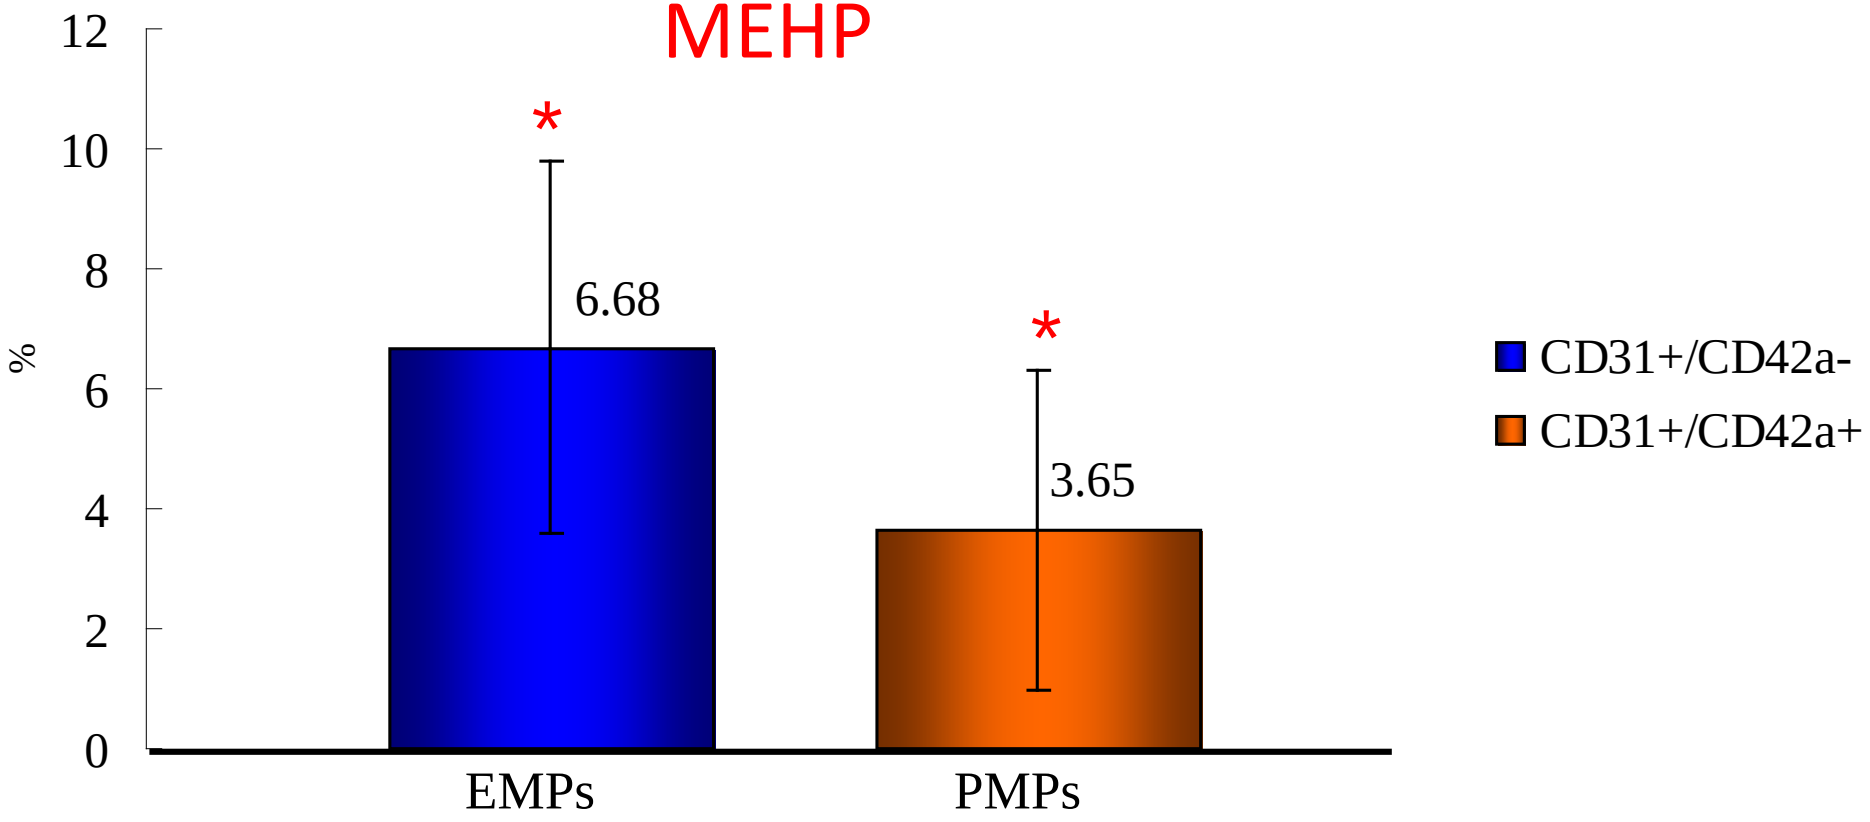
Figure 1. For every increase one Log-MEHP the increase of microparticles.



Adjusted for age, gender and other risk factors (smoking status, BMI, systolic BP, LDL-C, triglyceride, and HOMA-IR).

p-value: * <0.05, † <0.01, ‡ <0.005.

Figure 2. Estimated percentage (95% CI) in EMPs, PMPs for an IQR increase in the DEHP metabolites (adjusted Cr) in multiple linear regression models



Adjusted for age, gender and other risk factors (smoking status, BMI, systolic BP, LDL-C, triglyceride, and HOMA-IR). * p <0.05.

Conclusions and Perspectives

- A clear positive association was found between urinary concentrations of MEHP and microparticles from endothelium and platelets in adolescents or young adults.
- This study provides the scientific evidence of atherogenic effects of DEHP phthalates exposure.

Figure 2. Glycemic indices change for every one unit increase in seven log-transformed urinary phthalate metabolites among adolescents and young adults.

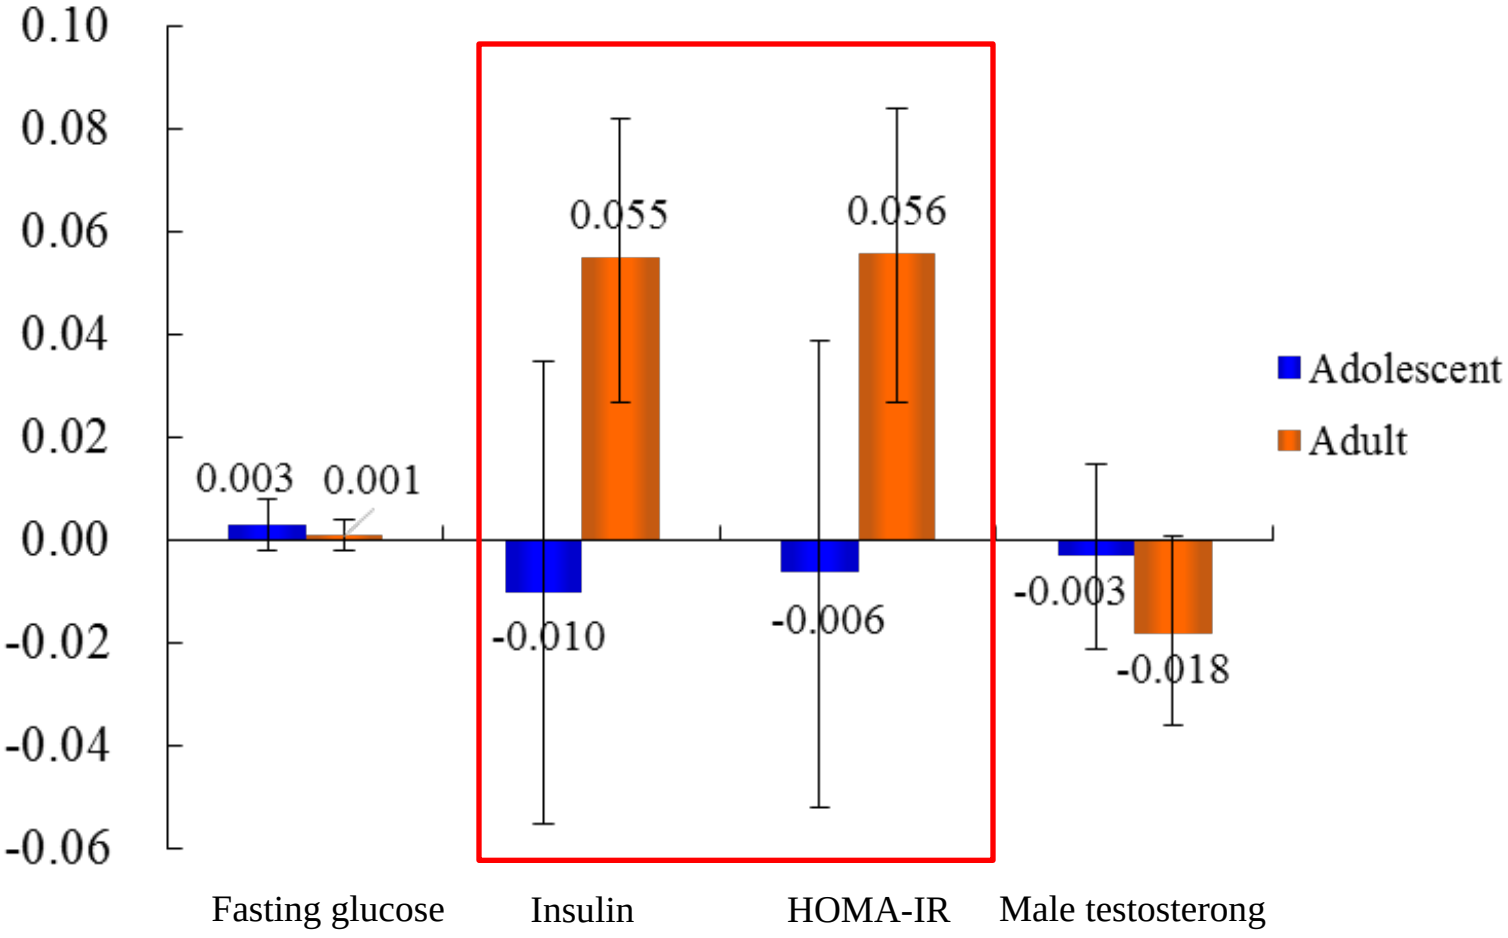

Fig 2. Schematic interconnections between urinary MEHP, male testosterone, and insulin resistance in young adults

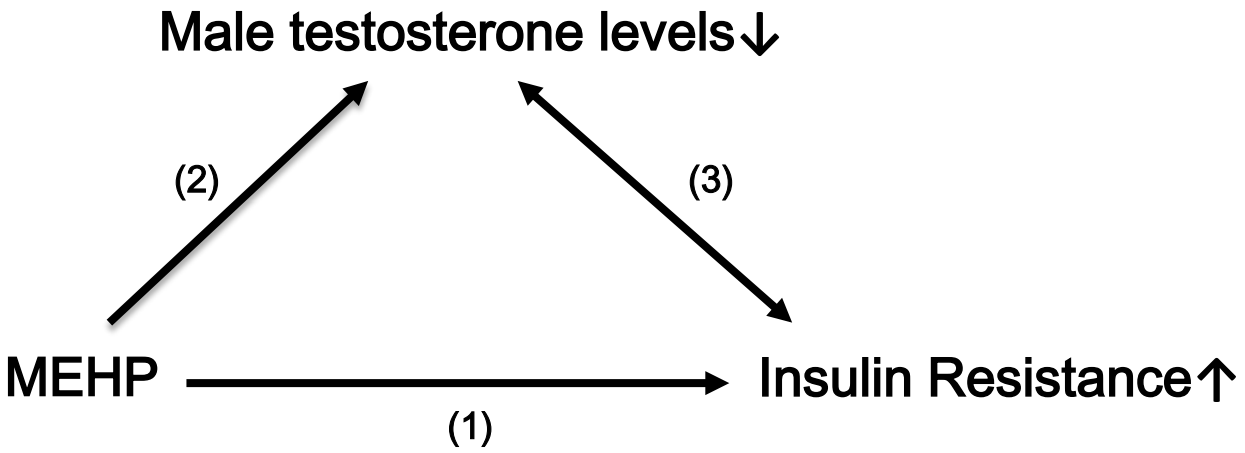

Fig. 2. Schematic interconnections between urinary MEHP metabolites, male testosterone, and insulin resistance in young adults. (1) Urinary MEHP metabolites are associated with increased insulin resistance. (2) Urinary MEHP metabolites are associated with lower male testosterone levels. (3) The male testosterone levels are inversely associated with increased insulin resistance.

Discussions

- Urinary **DEHP** metabolite, MEHP associate **with fasting insulin and HOMA-IR**, independent of covariates in young adults.
- Those of low risk subjects are susceptible groups, such as women, non-HTN, No smoking, No alcohol, and non-APOE4 carriers.
- This study highlighted the **diabetogenic potential** of phthalates exposure.

Positive Association between Urinary Concentration of Phthalate Metabolites and Oxidation of DNA and Lipid in Adolescents and Young Adults

Chien-Yu Lin[1,2], Pau-Chung Chen[3,4,5], Chia-Jung Hsieh[6], Chao-Yu Chen[7], Anren Hu[8], Fung-Chang Sung[9], Hui-Ling Lee[7] & Ta-Chen Su[3,10]

Phthalate has been used worldwide in various products for years. Little is known about the association between phthalate exposure and biomarkers of oxidative stress in adolescents and young adults. Among 886 subjects recruited from a population-based cohort during 2006 to 2008, 751 subjects (12–30 years) with complete phthalate metabolites and oxidation stress measurement were enrolled in this study. Nine urine phthalate metabolites, 8-hydroxydeoxyguanosine (8-OHdG), and 8-iso prostaglandin F2α (8-isoPGF2α) were measured in urine to assess exposure and oxidative stress to DNA and lipid, respectively. Multiple linear regression analysis revealed that an ln-unit increase in mono-methyl phthalate (MMP) concentration in urine was positively associated with an increase in urine biomarkers of oxidative stress (in μg/g; creatinine of 0.098 ± 0.028 in 8-OHdG; and 0.253 ± 0.051 in 8-isoPGF2α). There was no association between other eight phthalate metabolite concentrations and oxidative stress. In conclusion, a higher MMP concentration in urine was associated with an increase in markers of oxidative stress to DNA and lipid in this cohort of adolescents and young adults. Further studies are warranted to clarify the causal relationship between exposure to phthalate and oxidative stress.

Figure Gender difference of urinary phthalate metabolites levels

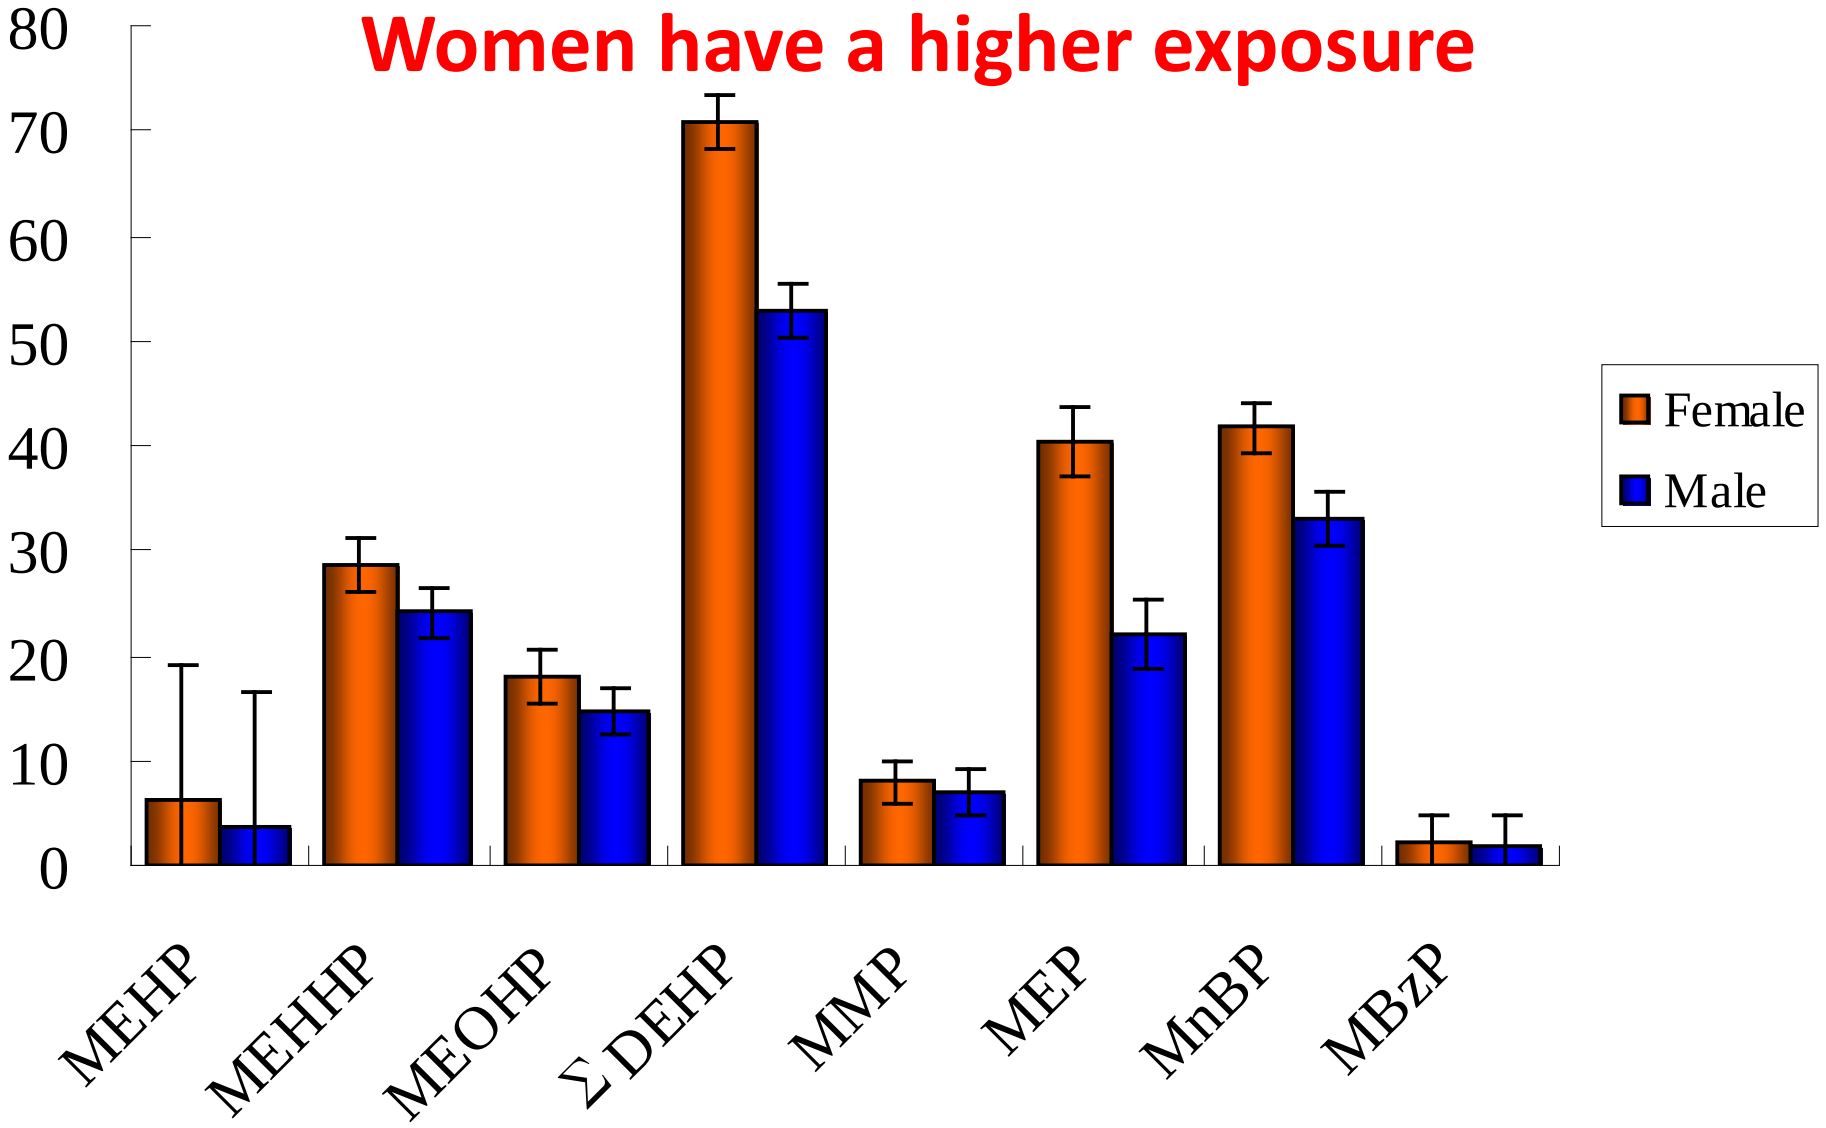

Figure BMI and urinary phthalate metabolites

Overweight have a higher exposure

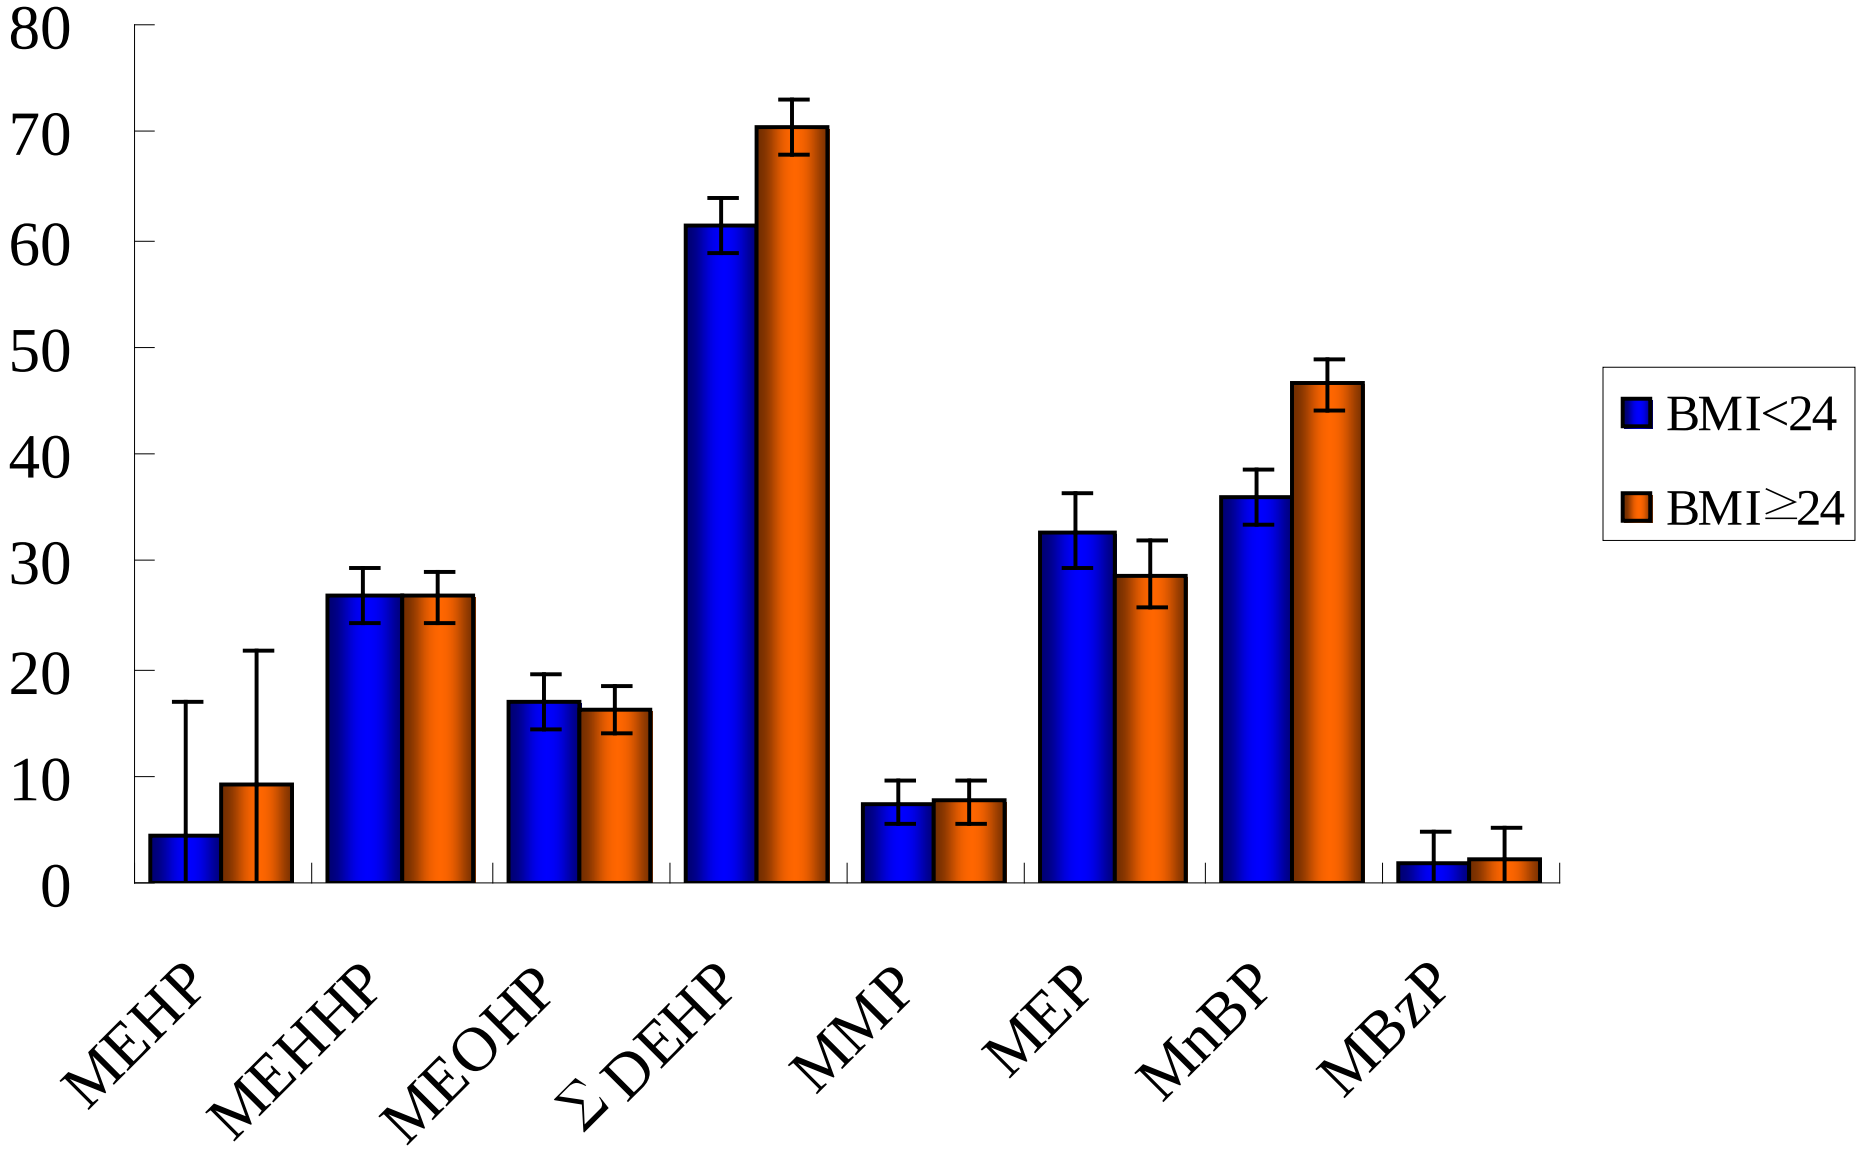

Figure 2. Creatinine-adjusted concentration of urinary phthalate metabolites by quartiles distribution of carotid IMT

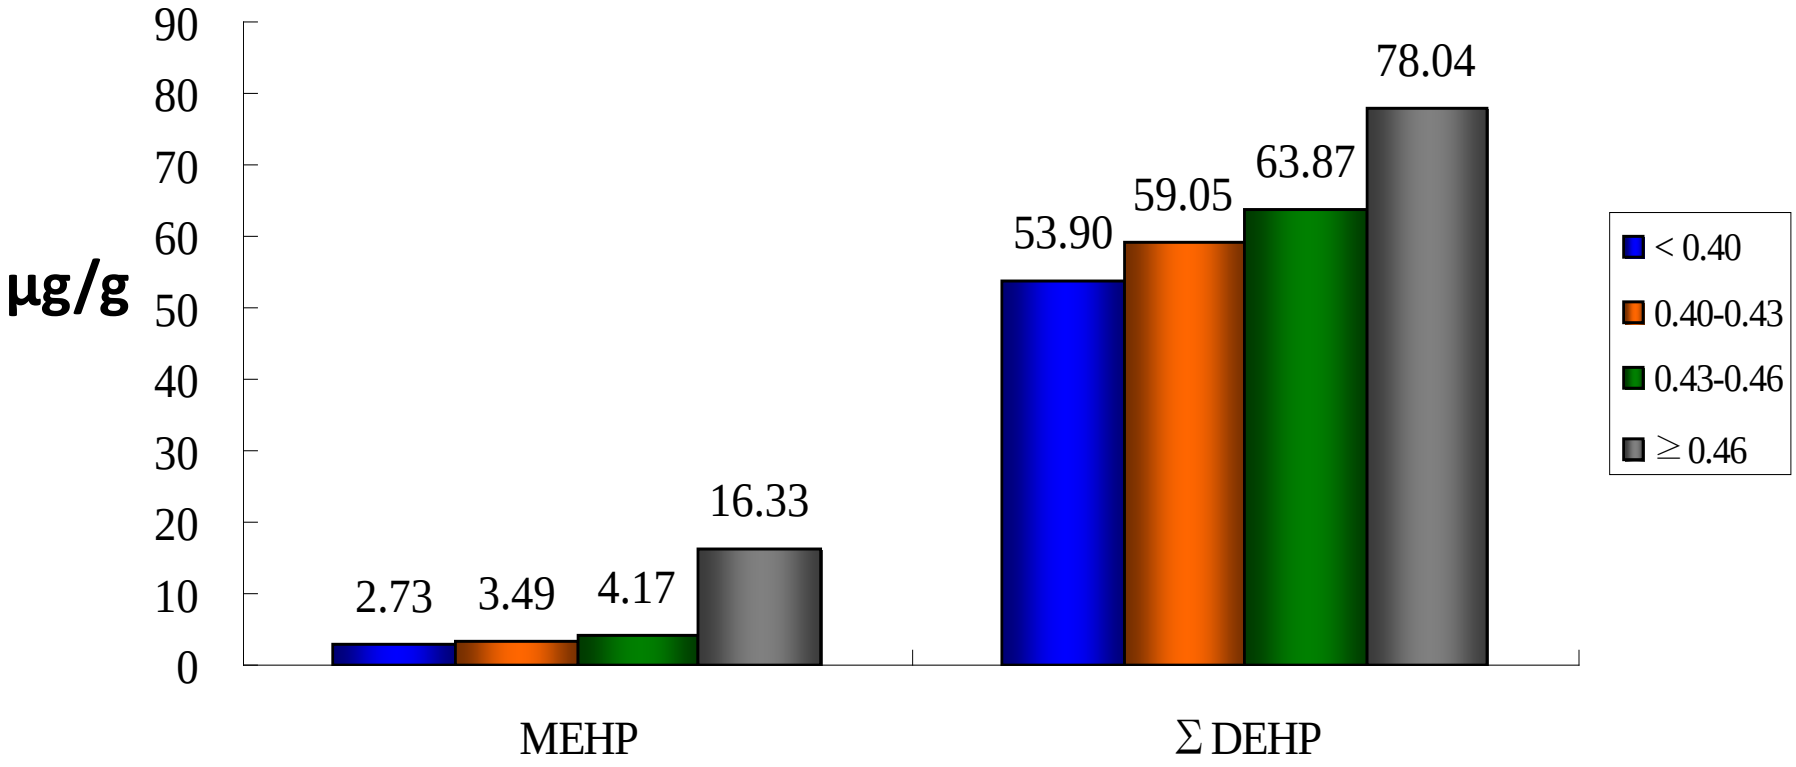

Figure 4-1. Carotid intima-media thickness across quartiles of MEHP concentration in linear regression models

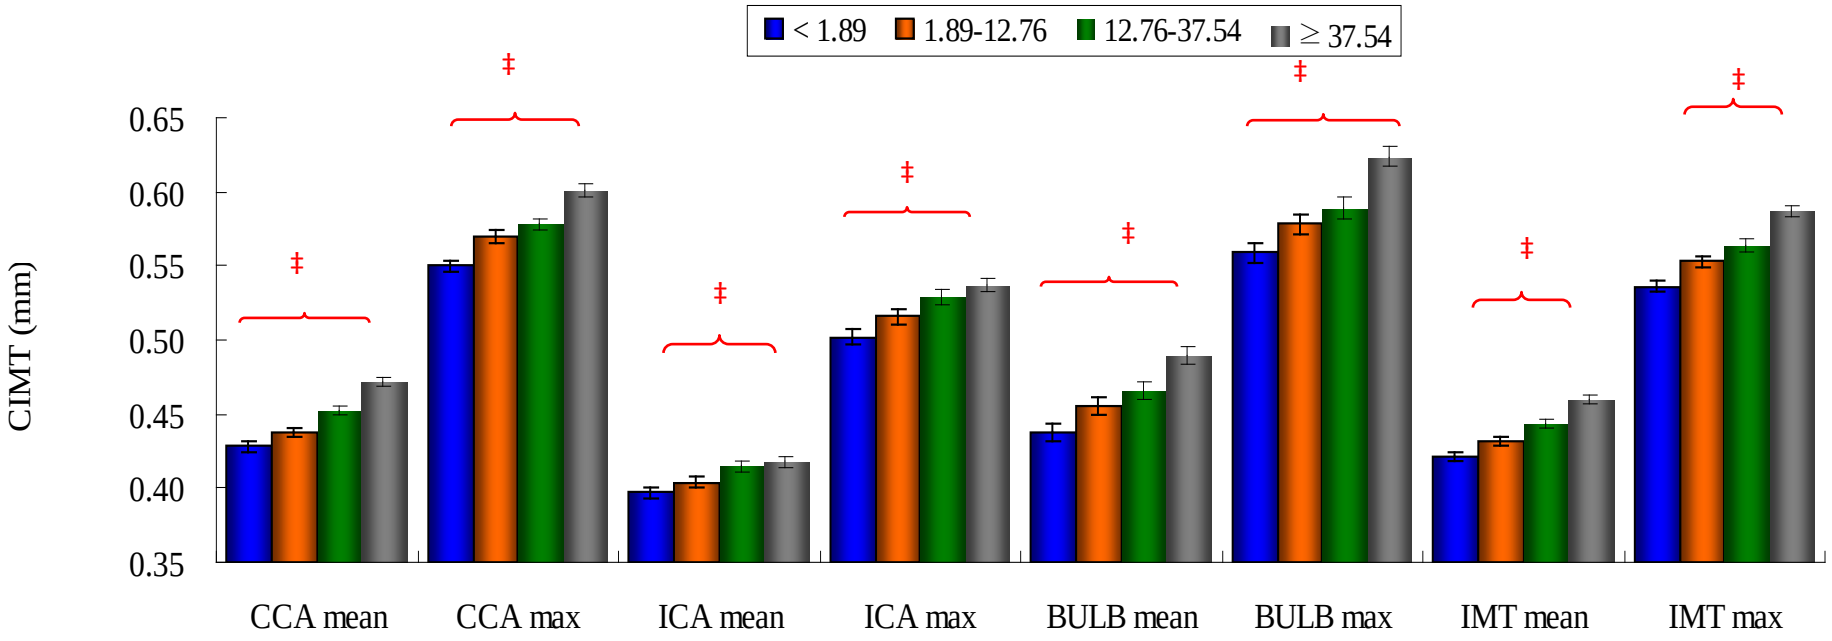
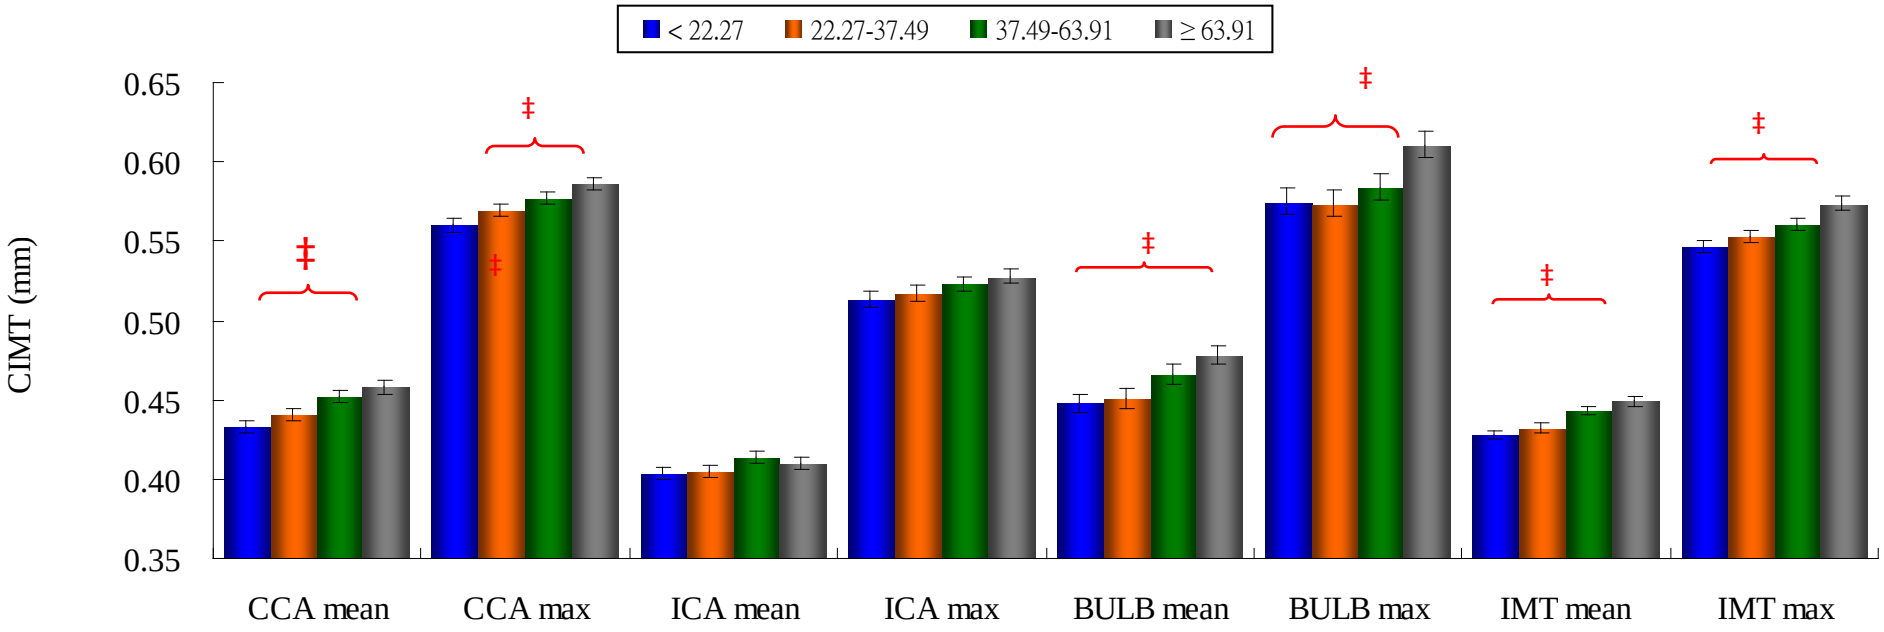


p-value: * <0.05, † <0.01, ‡ <0.005.

Least square mean and standard error after adjustment for age, gender, body mass index, glucose, cholesterol, hypertension, smoking and drinking habit, hs-CPR, household income.

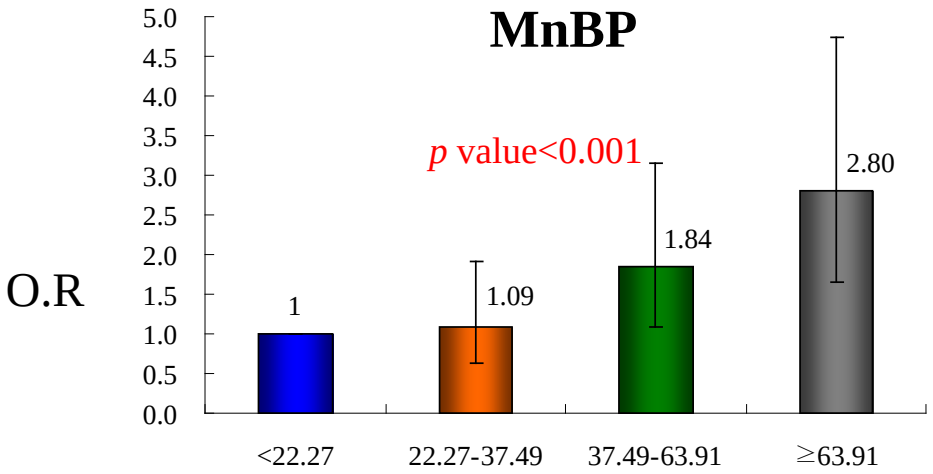
Figure 4-3. Carotid intima-media thickness (CIMT) in mm across quartiles of MnBP concentration in linear regression models.



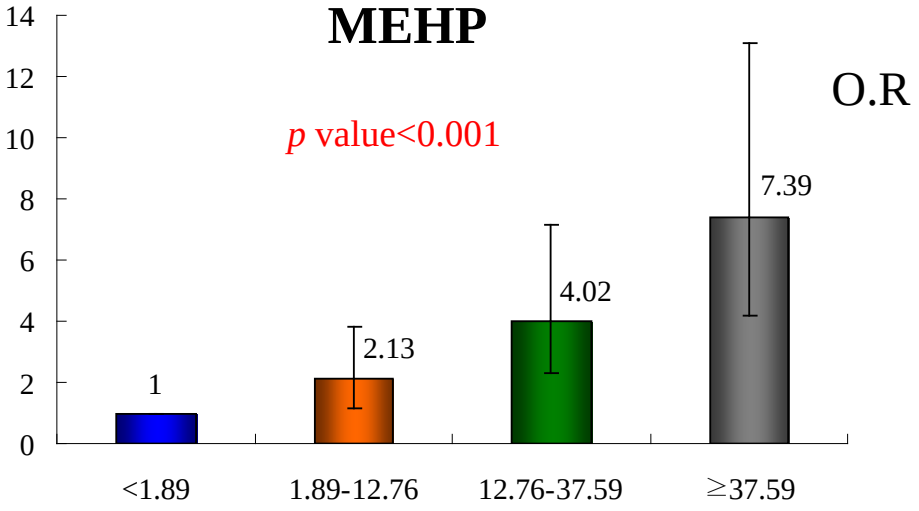
p-value: * <0.05, † <0.01, ‡ <0.005.

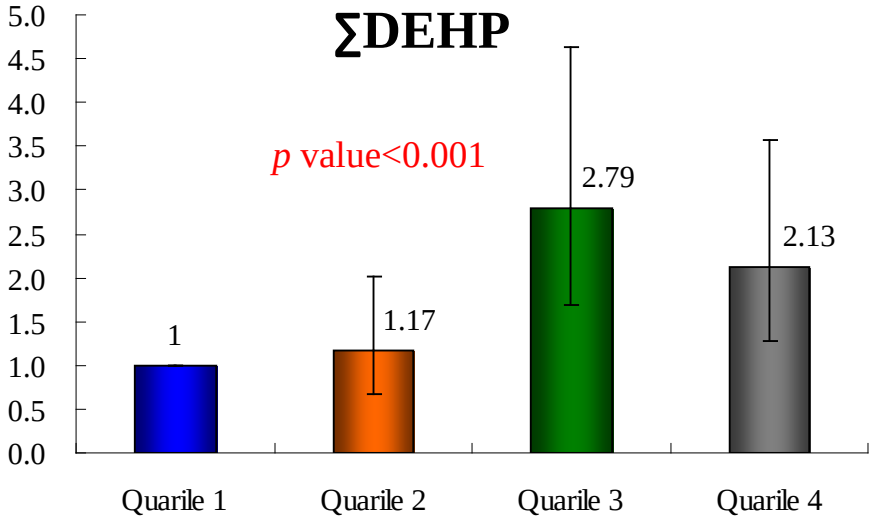
Least square mean and standard error after adjustment for age, gender, body mass index, glucose, cholesterol, hypertension, smoking and drinking habit, hs-CPR, household income.

Figure 4. Multivariate logistic regression analysis for the risk of thicker carotid intima-thickness (CIMT ≥75th percentile) by quartile distribution of urinary phthalate metabolites.



Models were adjusted for age, gender, body mass index, cholesterol, hypertension, smoking and drinking habit, hs-CPR, household income.





Discussions

- Urinary phthalate (**DEHP)** metabolites are significantly and positively associated with **carotid IMT, including CCA, ICA, and bulb, and mean IMT** after controlling associated covariates.
- The major phthalate esters related with subclinical atherosclerosis are **MnBP, MEHP and ΣDEHP**.
- The associations in relative healthy young adults and adolescents indicate the evidence is very important and not by chance.

Urinary Phthalate Metabolite Concentrations and Diabetes among Women in the National Health and Nutrition Examination Survey (NHANES) 2001–2008

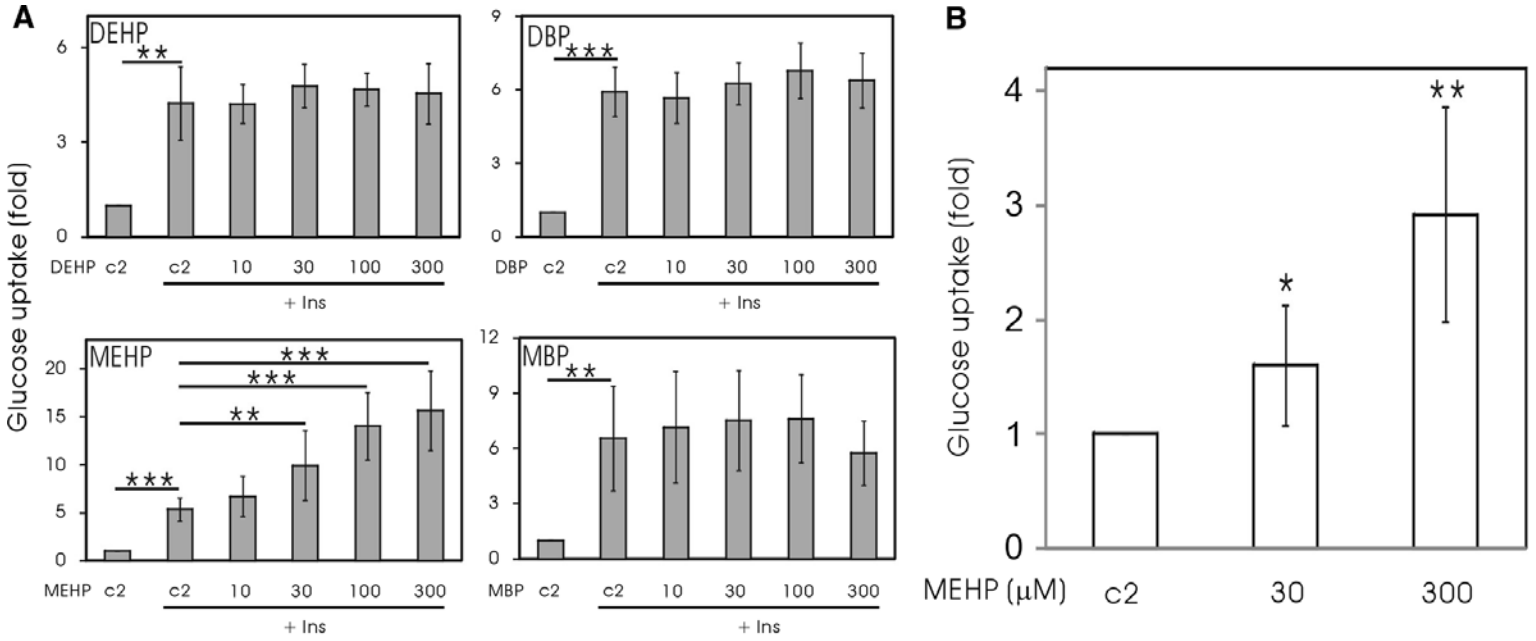
Q, quartile. For each of the phthalate categories, Q1 is the reference.

Mono(2-ethylhexyl)phthalate accumulation disturbs energy metabolism of fat cells

(Chiang H.C. et al., *Arch Toxicol* 2016;90(3):589–601.)

- In vitro evidence of MEHP impacts on lipolysis, glucose uptake/glycolysis, and mitochondrial respiration/biogenesis demonstrates that MEHP accumulation disturbs energy metabolism of fat cells.

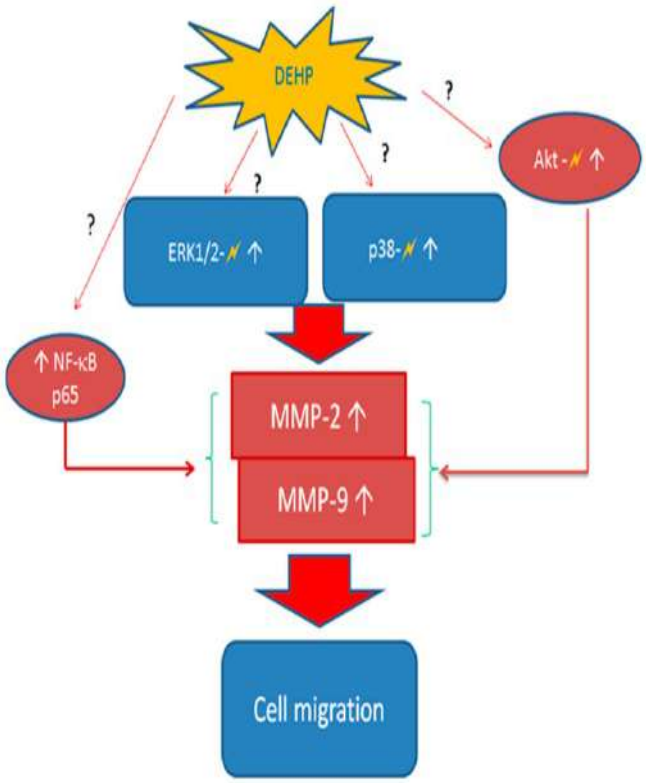


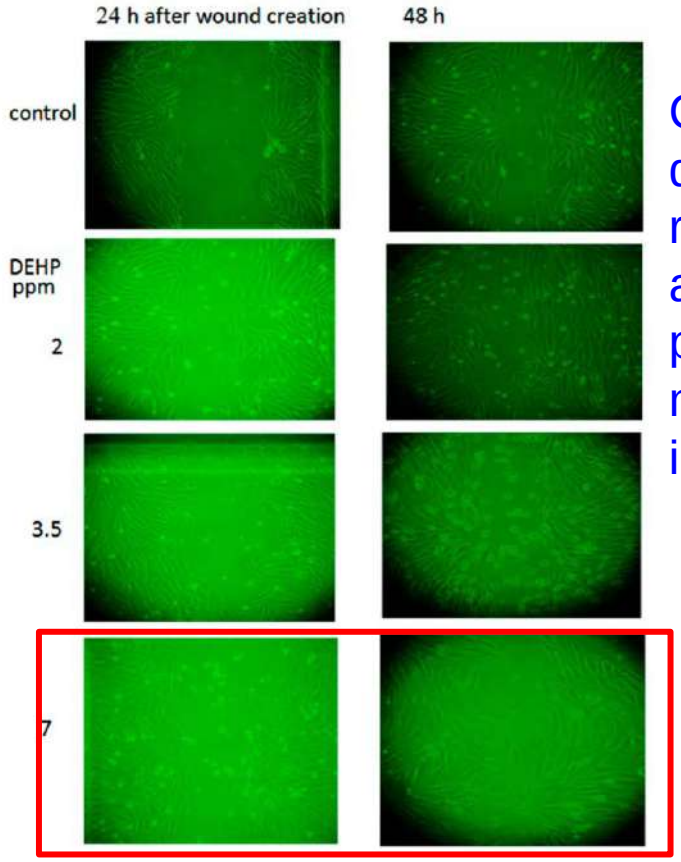
-MEHP-treated adipocytes displayed significant increases in glucose uptake.
-MEHP treatment during adipogenesis might alter the normal gene expression pattern and led to the consequent changes in insulin sensitivity.

Possible Mechanisms of Di(2-ethylhexyl) Phthalate-Induced MMP-2 and MMP-9 Expression in A7r5 Rat Vascular Smooth Muscle Cells

(Shih M.F. et al., *Int. J. Mol. Sci.* 2015;16(12):28800–28811)

- DEHP can be a potent inducer of atherosclerosis by increasing MMP-2 and MMP-9 expression at least through the regulations of p38 MAPK, ERK1/2, Akt, and NF-κB.





Cardiovascular disorders is often related to the abnormal proliferation and migration of VSMC in arterial wall

DEHP at doses higher than 3.5 ppm would induce cell migration

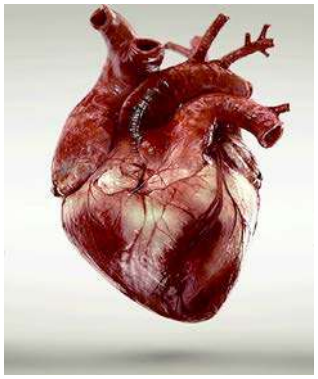
Carotid IMT ⇒ **CHD**

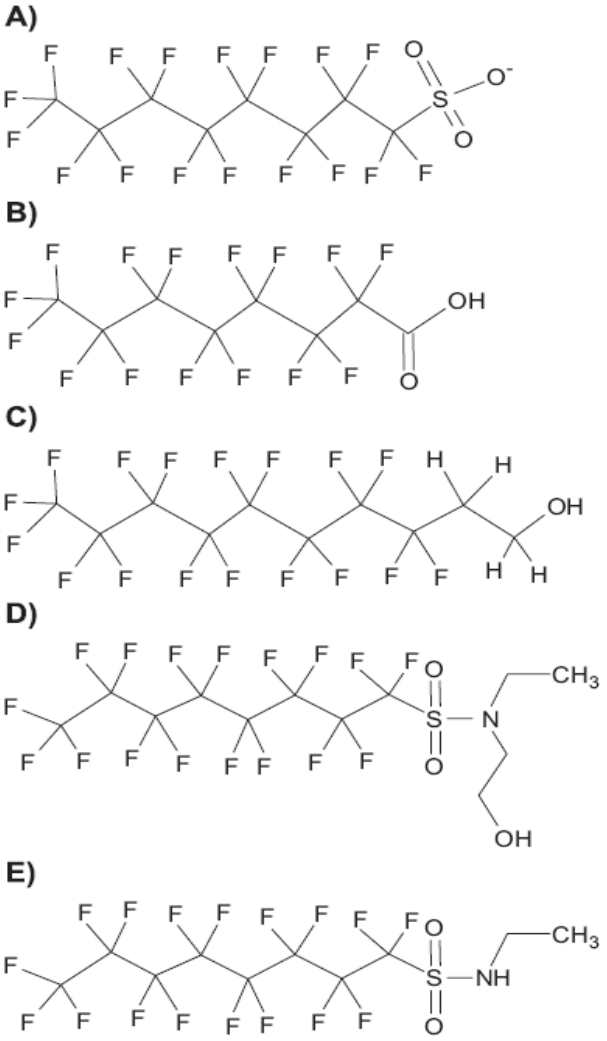


Perfluorinated Chemicals and Cardiometabolic Health

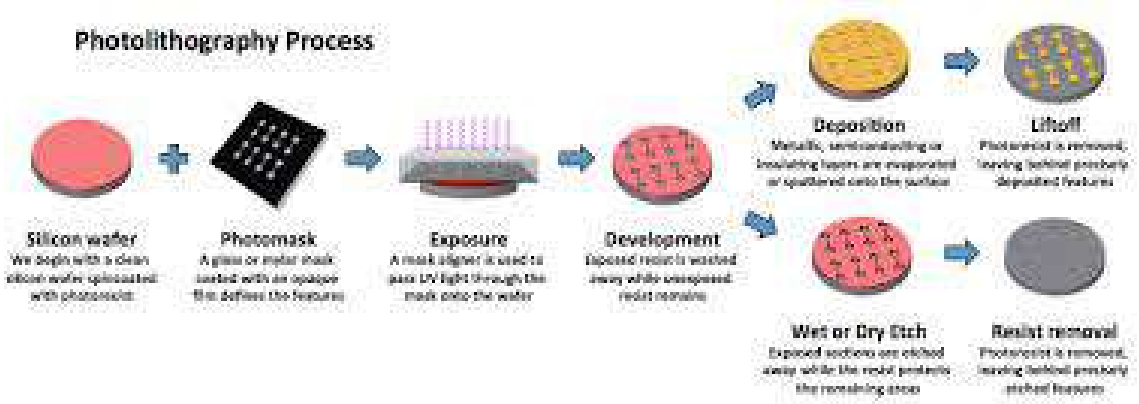
Ta-Chen Su

Introduction

- Perfluorinated chemicals (PFCs) consist of a 4 to 14 carbon backbone and a charged functional moiety (primarily carboxylate, sulfonate, or phosphonate).
- PFCs are man-made chemicals that have only been used in the last half century.
- The two most widely known PFCs are perfluorooctane sulfate (**PFOS**) **and perfluorooctanoic acid (PFOA)**



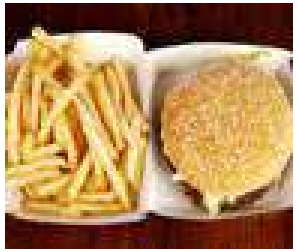
Chemical structure of PFCs.
(A) Perfluorooctane sulfonate (PFOS),
(B) perfluorooctanoate (PFOA),
(C) 1-hydroxyethane-2-perfluorooctanol(8:2 FTOH),
(D) N-ethyl perfluorooctane sulfonamidothanol (NEtFOSE),
(E) N-ethyl perfluorooctane sulfonamide (NEtFOSA).



Perfluorinated chemicals, PFCs

- Stable in air, nonflammable, not degraded by strong acids, alkalis or oxidizing agents.
- Surfactants, lubricants, polishes, food packaging, and fire-retardant foams

- The unique stability: nonbiodegradable and very persistent in the environment

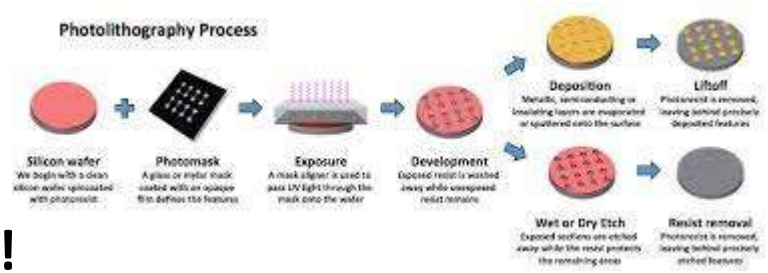


Perfluorinated chemicals, PFCs

- PFCs are a large group of manufactured compounds that are widely used to make everyday products more resistant to stains, grease, and water.
- For example, PFCs may be used to keep food from sticking to cookware, to make sofas and carpets resistant to stains, to make clothes and mattresses more waterproof, and may also be used in some food packaging, as well as in some firefighting materials.
- Because they help reduce friction, they are also used in a variety of other industries, including aerospace, automotive, building and construction, and electronics.
- **Semiconductive Company:**

  Photolithography

  (Many factories in Taiwan)



- **Long half life and bioaccumulative!!**
- PFCs have been demonstrated to associate with insulin resistance and glucose homeostasis (Lin CY, Diabetes Care 2009).

Introduction

- Possible exposure pathways:
  Drinking water
  Food
  Dust in homes
  Migration from food packaging and cookware

- **Half life:**

The longer the carbon chain length, the longer PFCs persists in the body.

4-carbon: perfluorobutane sulfonate = 1 month

8-carbon: PFOA = 3.8 years

PFOS = 5.4 years

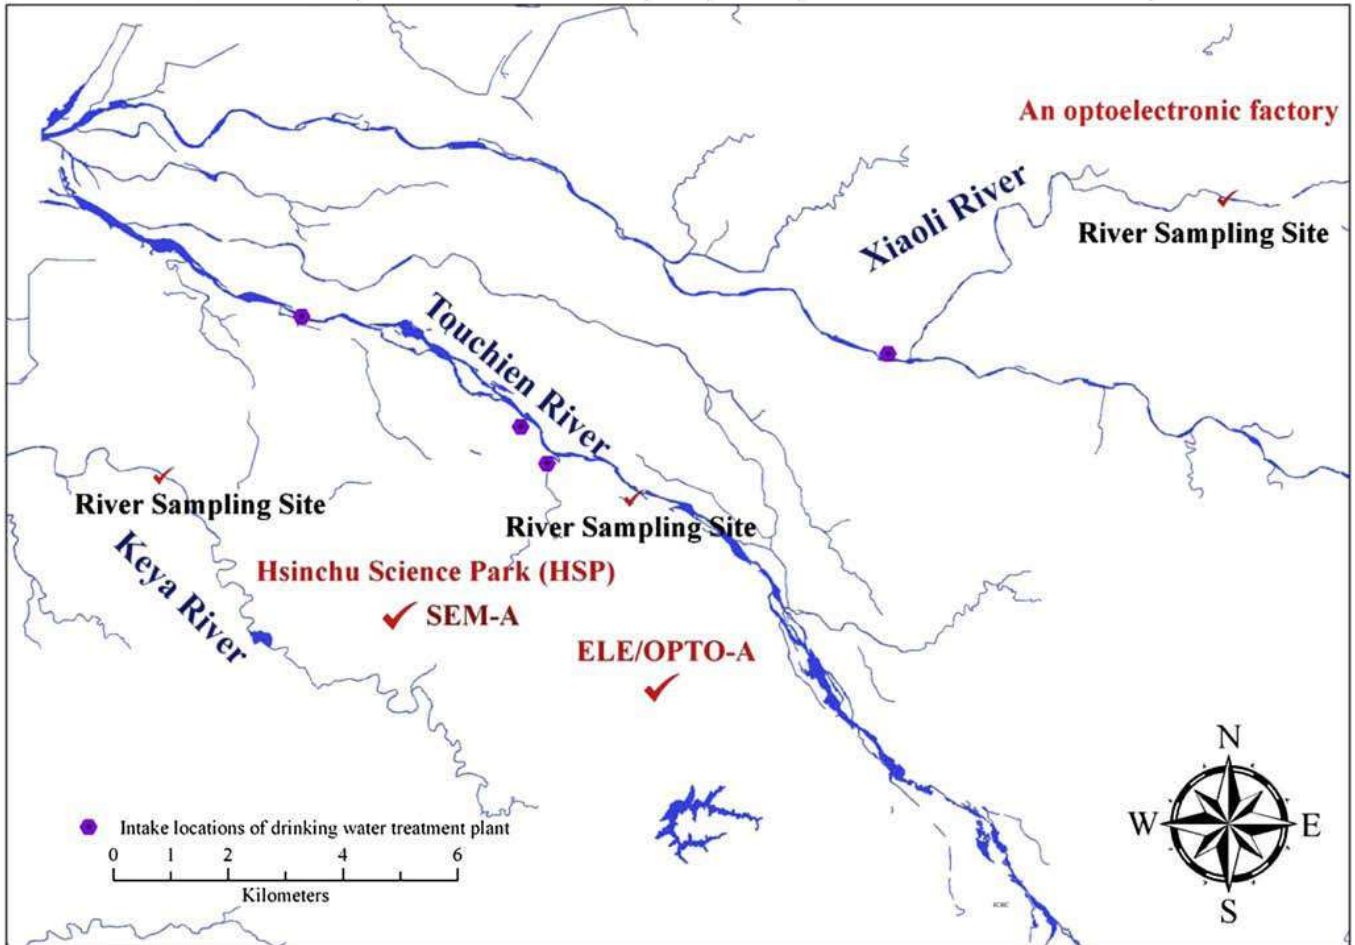
The impact of semiconductor, electronics and optoelectronic industries on downstream perfluorinated chemical contamination in Taiwanese rivers

Angela Yu-Chen Lin*, Sri Chandana Panchangam, Chao-Chun Lo

National Taiwan University, Graduate Institute of Environmental Engineering, No. 1, Sec. 4, Roosevelt Road, Taipei 10617, Taiwan

The semiconductor, electronics and optoelectronic industries are the primary source of PFC contamination in downstream aqueous environments.



PFOA, PFOS, and PFDA levels in Hsin-Chu Rivers

Table 4
PFOA, PFOS, and PFDA concentrations detected in Taiwanese River waters and compared with previous studies around the globe.

Region	Occurrence area	Impact	PFOA (ng/L)	PFOS (ng/L)	PFDA (ng/L)	Ref.

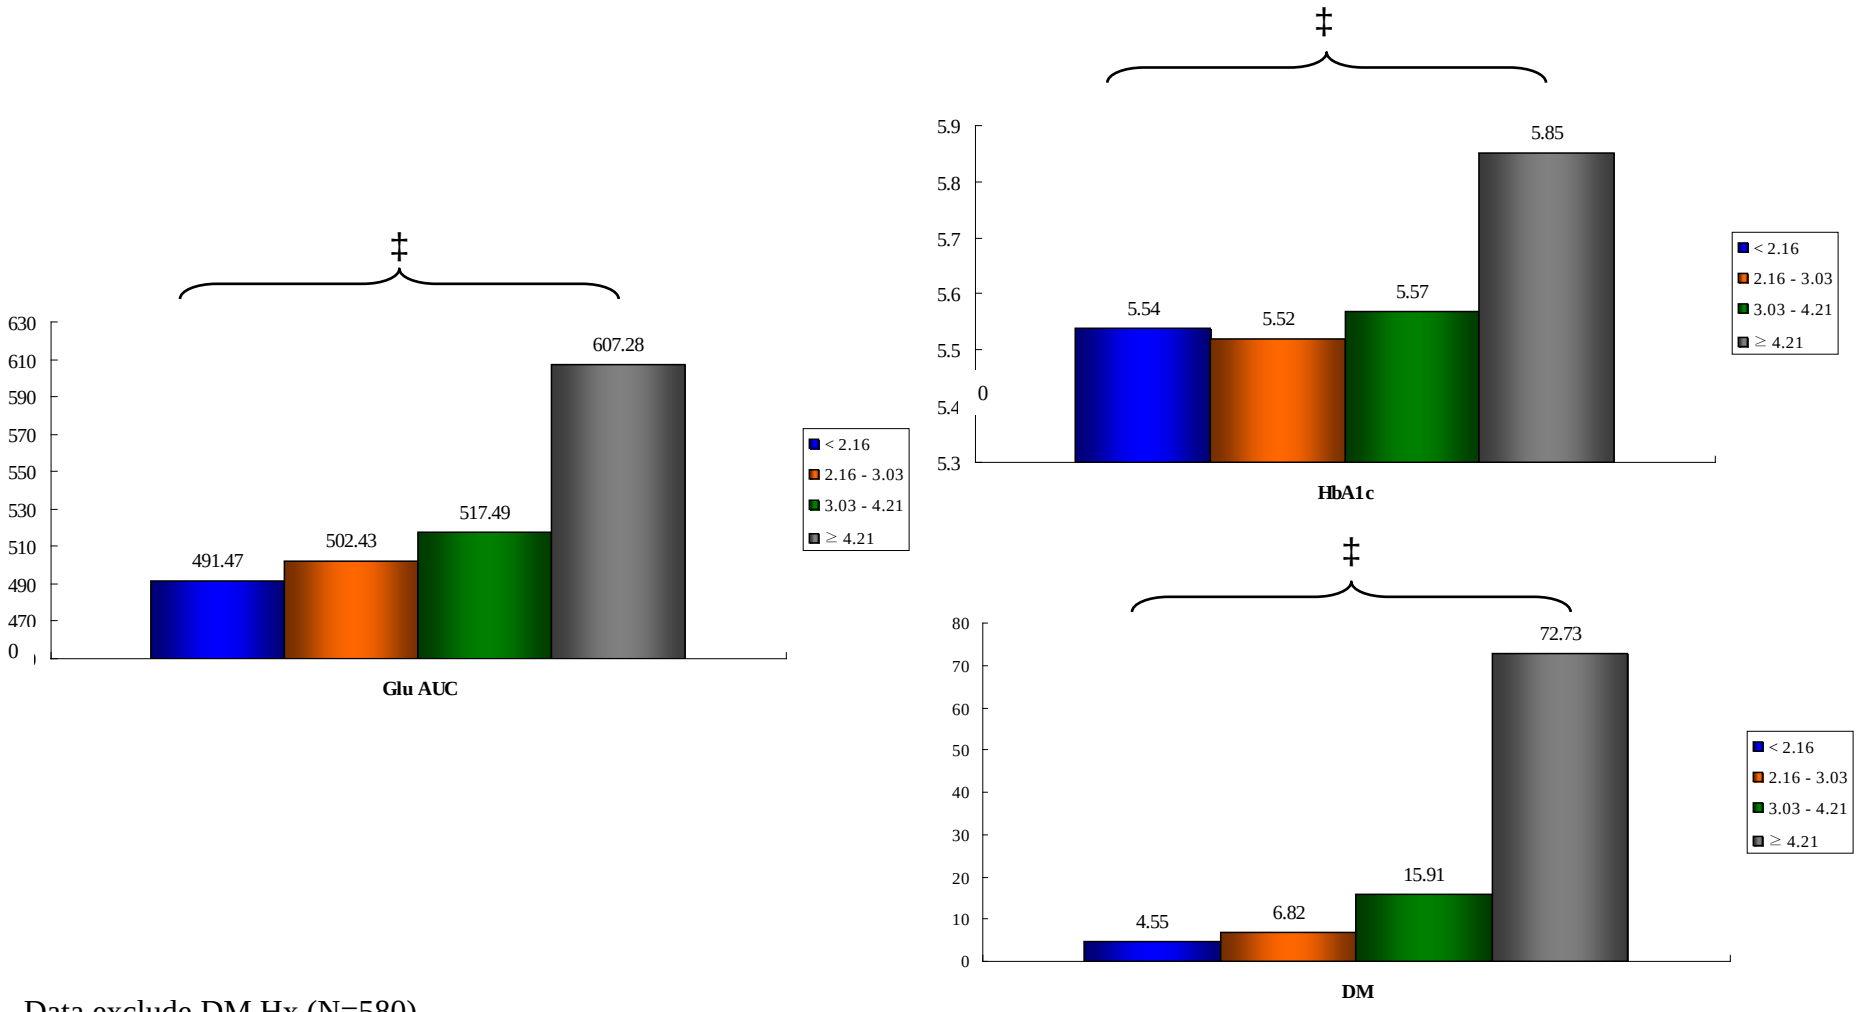
Su et al., Environmental International 2016 March

Material and Methods

- Between 2009 and 2011, 592 adults aged 35–65 years who attended a cohort study of work- and environment-related cardiovascular diseases as the control subjects of acute CHD in National Taiwan University Hospital.
- 571 middle-aged (age range, 20–60 years old) adults without clinical diabetes (fasting levels < 7.0 mmol/L) or known history of CHD or stroke completed a **standard 2-h oral glucose tolerance test** (OGTT) (75-g glucose in 300 mL water) and had **plasma PFCs** measurements were included in this analysis.

Figure 1. Trend Test of Glycemic Indices According to Quartile Distribution of Serum PFOS Levels



Data exclude DM Hx (N=580)

Glu AUC and HbA1c were adjusted for age, gender, BMI, hypertension, hypercholesterolemia, smoking, drinking and individual income.

p-value for these parameters * P <0.05, † <0.01, ‡ <0.005

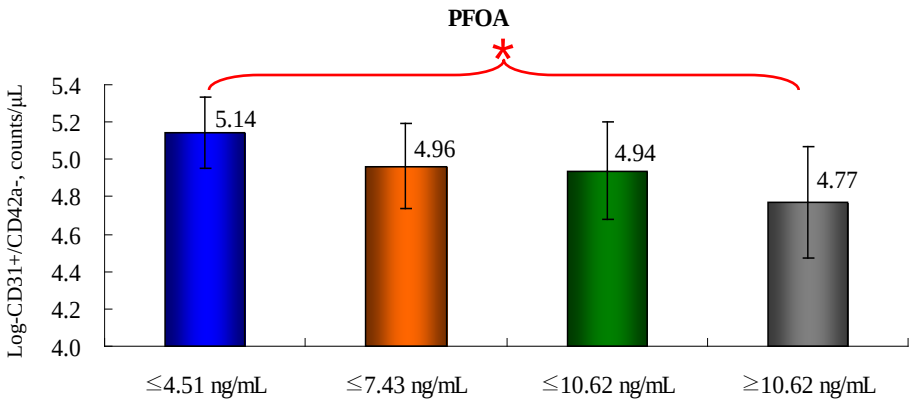
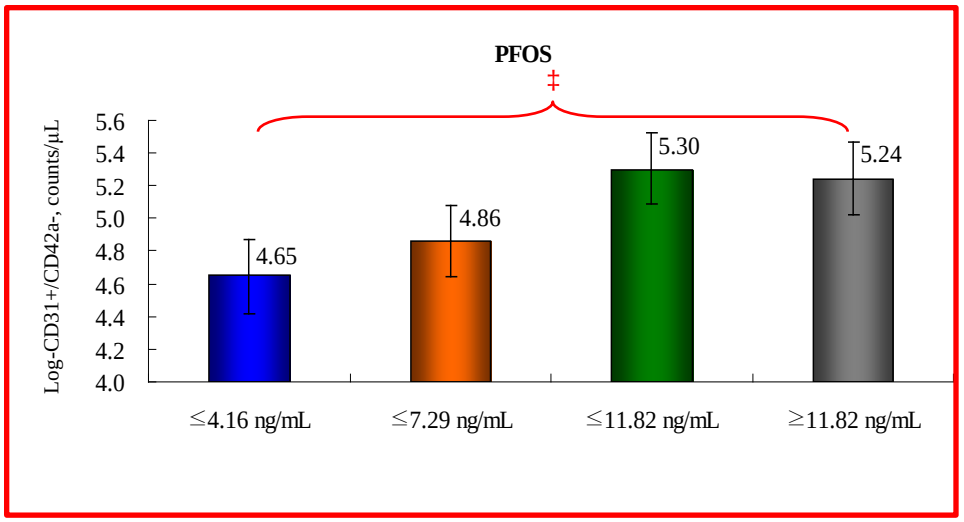
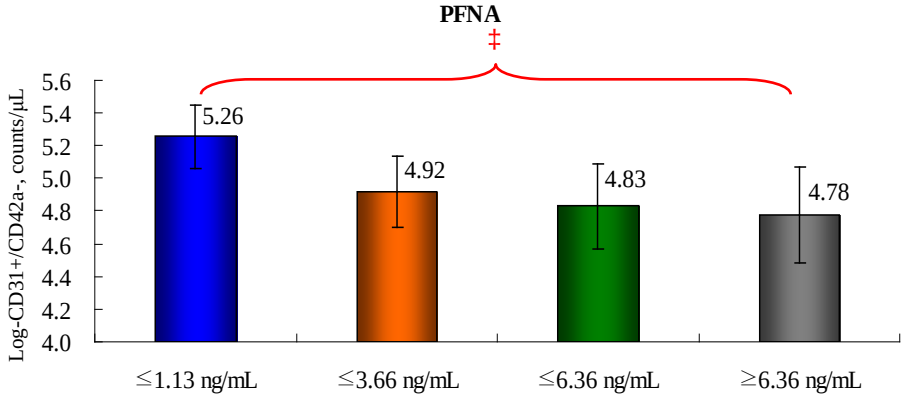
and 8-OHdG. In conclusion, we found the positive association between PFOS and CIMT that was more evident when serum levels of EMPs (CD31 +/CD42a −) and PMPs (CD31 +/CD42a +) were elevated. Further studies are warranted to investigate the causal inference of PFOS exposure on endothelial cell damage and atherosclerosis.

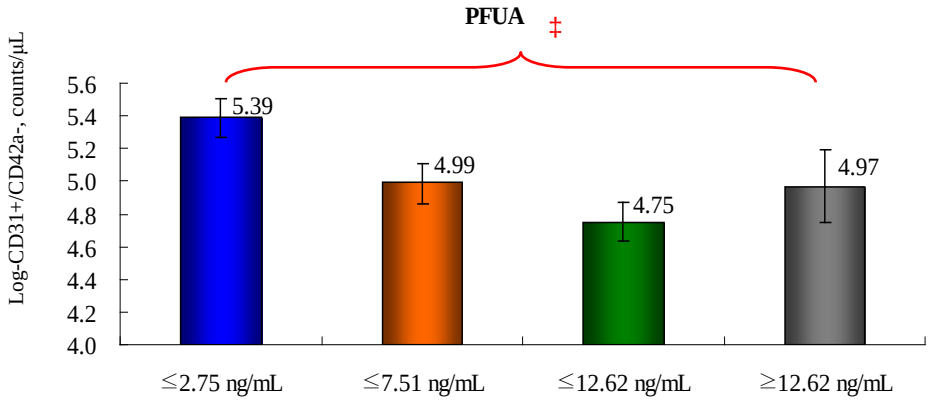
Environment International 94 (2016), 292–299

Figure 1. Mean and 95% C. I. of adjusted markers of EMPs across categories of PFCs in linear regression models (n = 848).





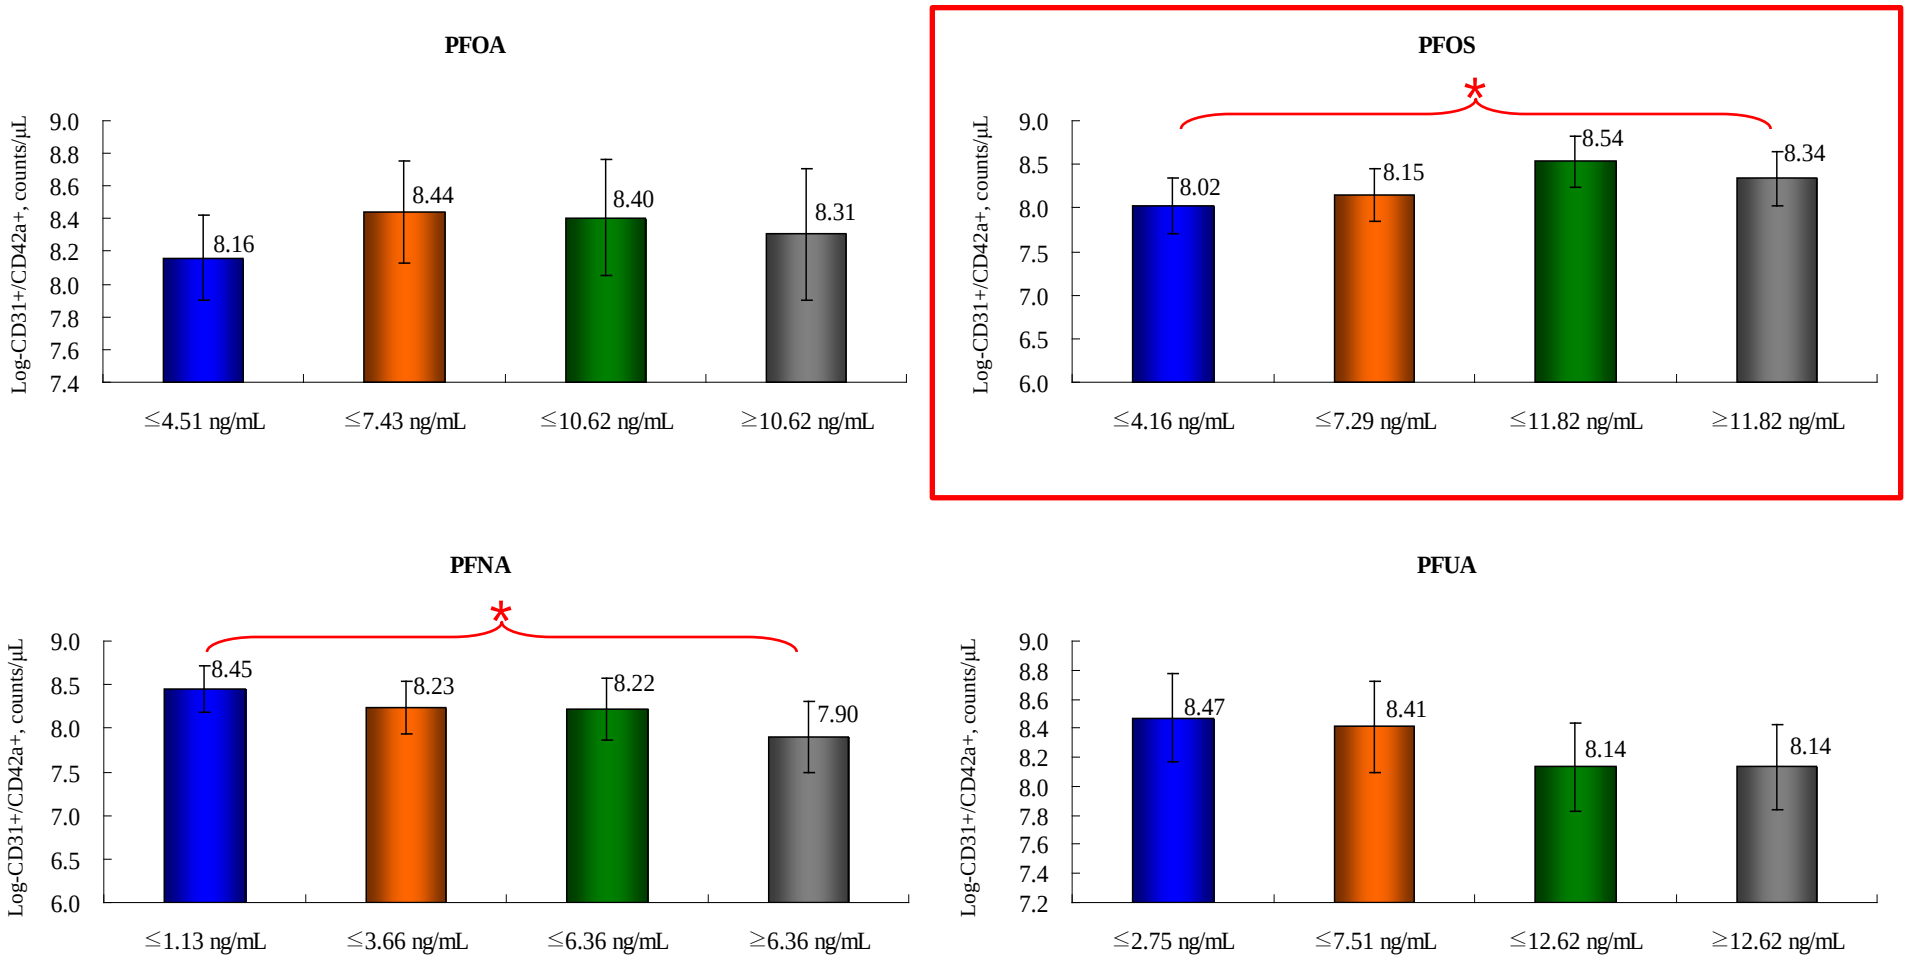




p-value: * <0.05, † <0.01, ‡ <0.005

Adjusted for age, gender and other risk factors (smoking status, body mass index, systolic blood pressure, low density lipoprotein, triglyceride, homeostasis model assessment of insulin resistance, and high sensitivity C-reactive protein).

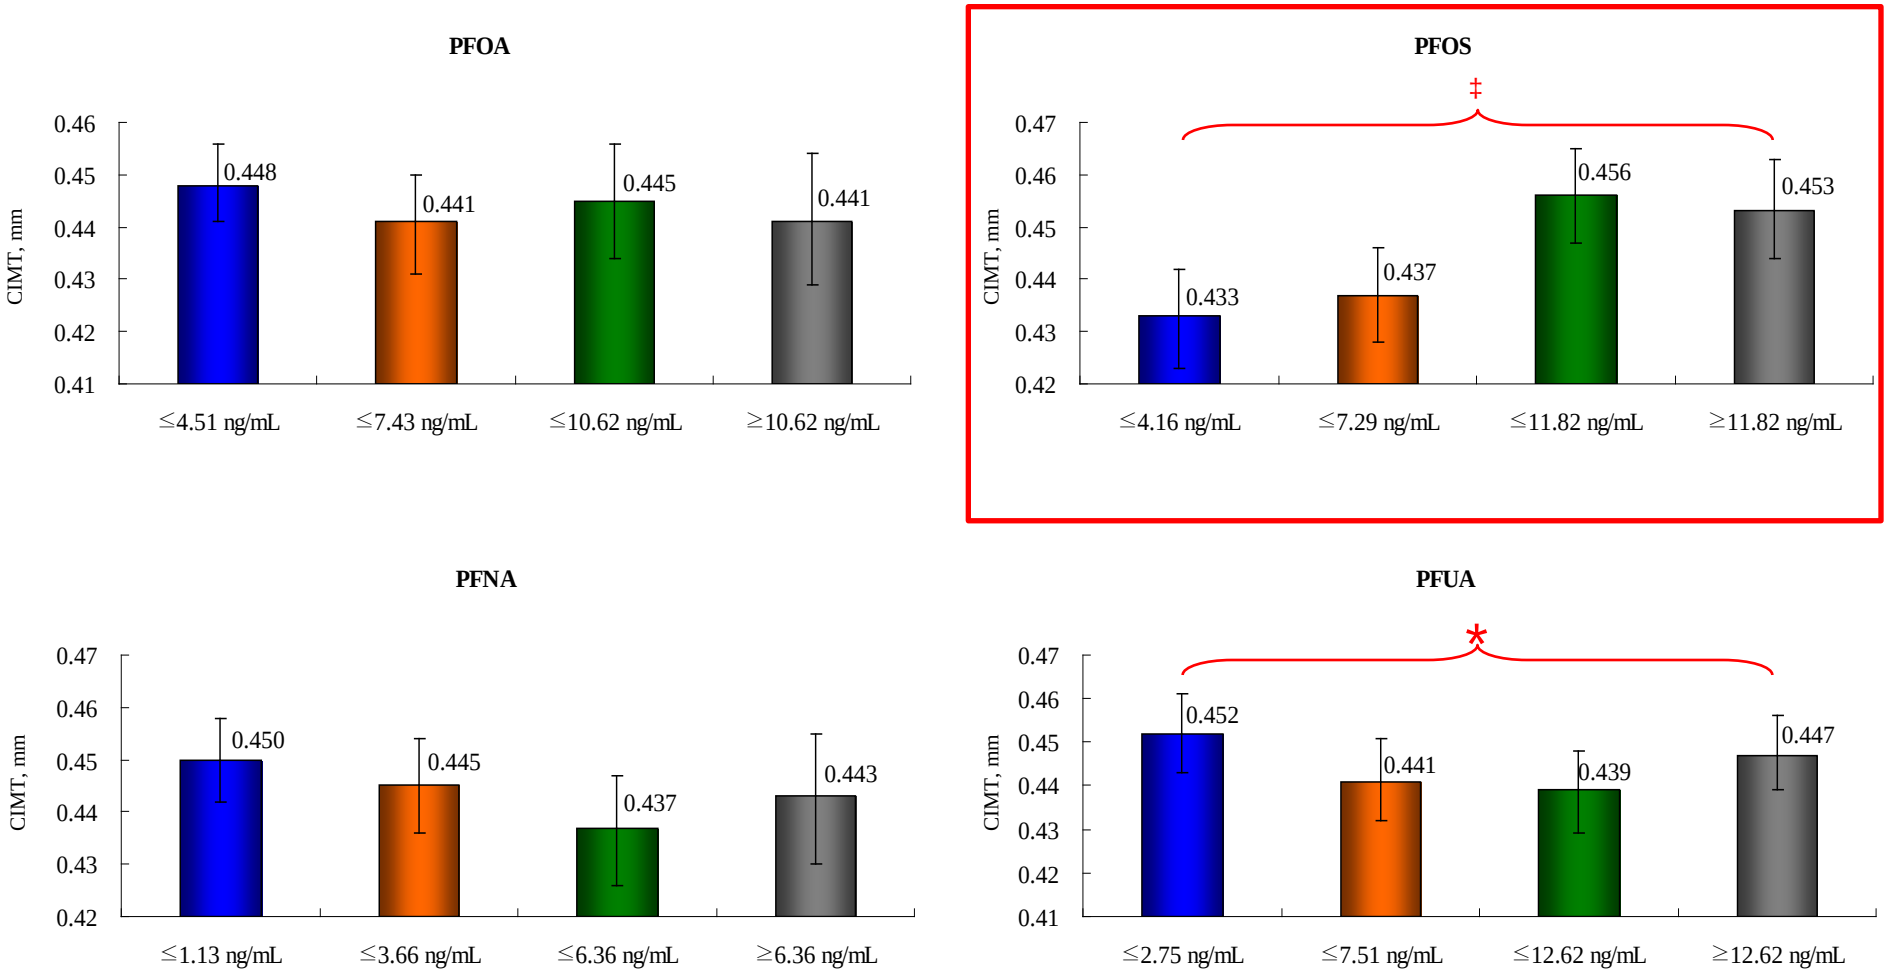
Figure 2. Mean and 95% C. I. of adjusted markers of PMPs across categories of PFCs in linear regression models (n = 848).



p-value: * <0.05, † <0.01, ‡ <0.005

Adjusted for age, gender and other risk factors (smoking status, body mass index, systolic blood pressure, low density lipoprotein, triglyceride, homeostasis model assessment of insulin resistance, and high sensitivity C-reactive protein).

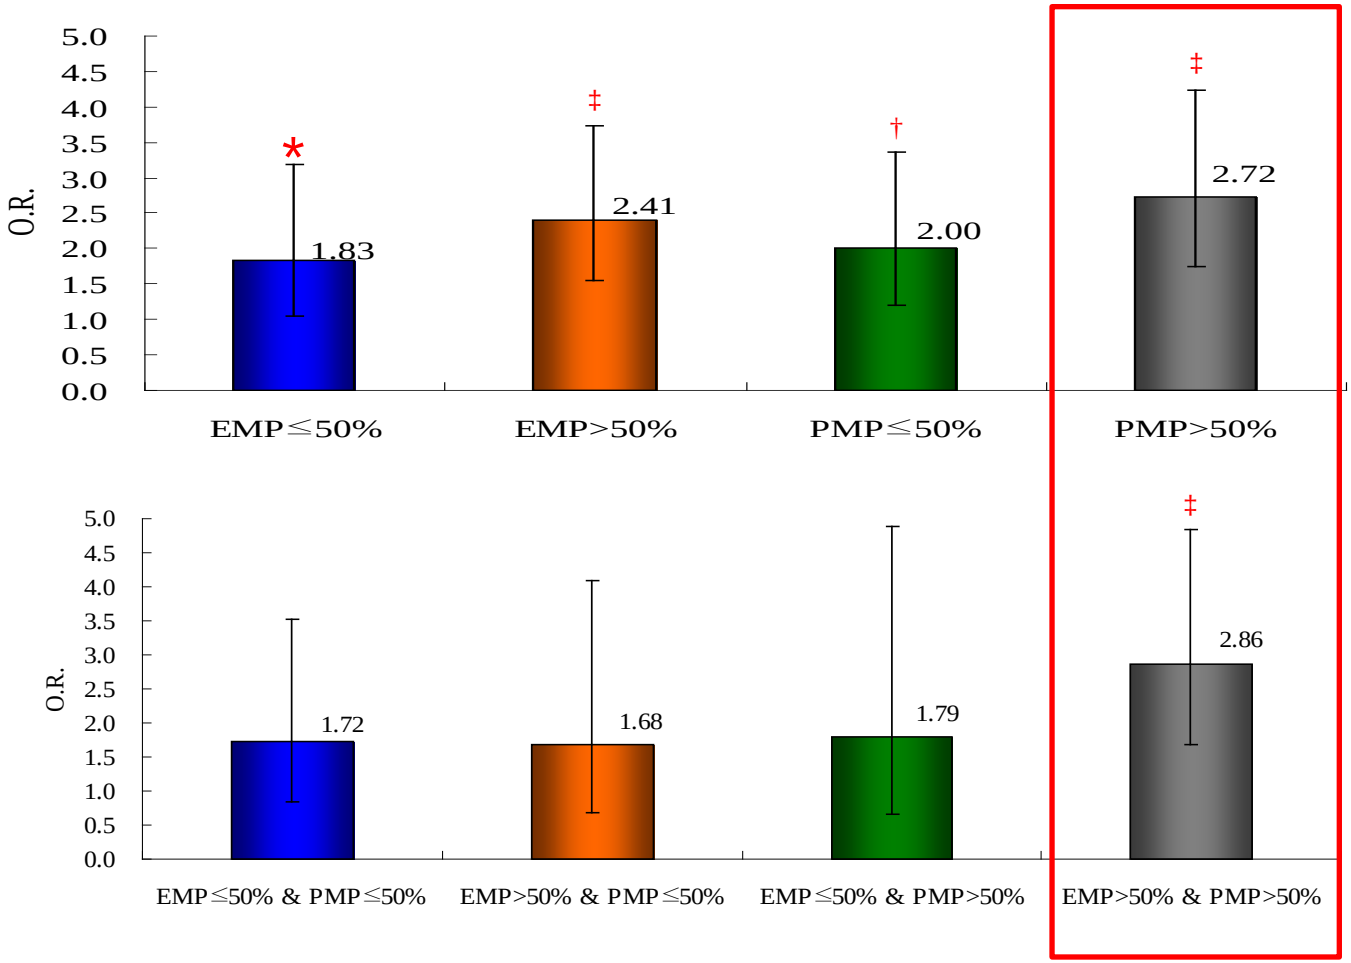
Figure 4. Mean and 95% C. I. of adjusted markers of CIMT across categories of PFCs in linear regression models (n = 848).



p-value: * <0.05, † <0.01, ‡ <0.005

Adjusted for age, gender and other risk factors (smoking status, body mass index, systolic blood pressure, low density lipoprotein, triglyceride, homeostasis model assessment of insulin resistance, and high sensitivity C-reactive protein).

Figure 5. Odds ratios (ORs) (95% C.I.) of thicker CIMT (greater than 50th percentile) with higher serum PFOS concentration (greater than 50%) by different categories of EMPs and PMPs concentrations.



p-value: * <0.05, † <0.01, ‡ <0.005

Adjusted for age, gender, smoking status, body mass index, systolic blood pressure, low density lipoprotein, triglyceride, homeostasis model assessment of insulin resistance, and high sensitivity C-reactive protein.

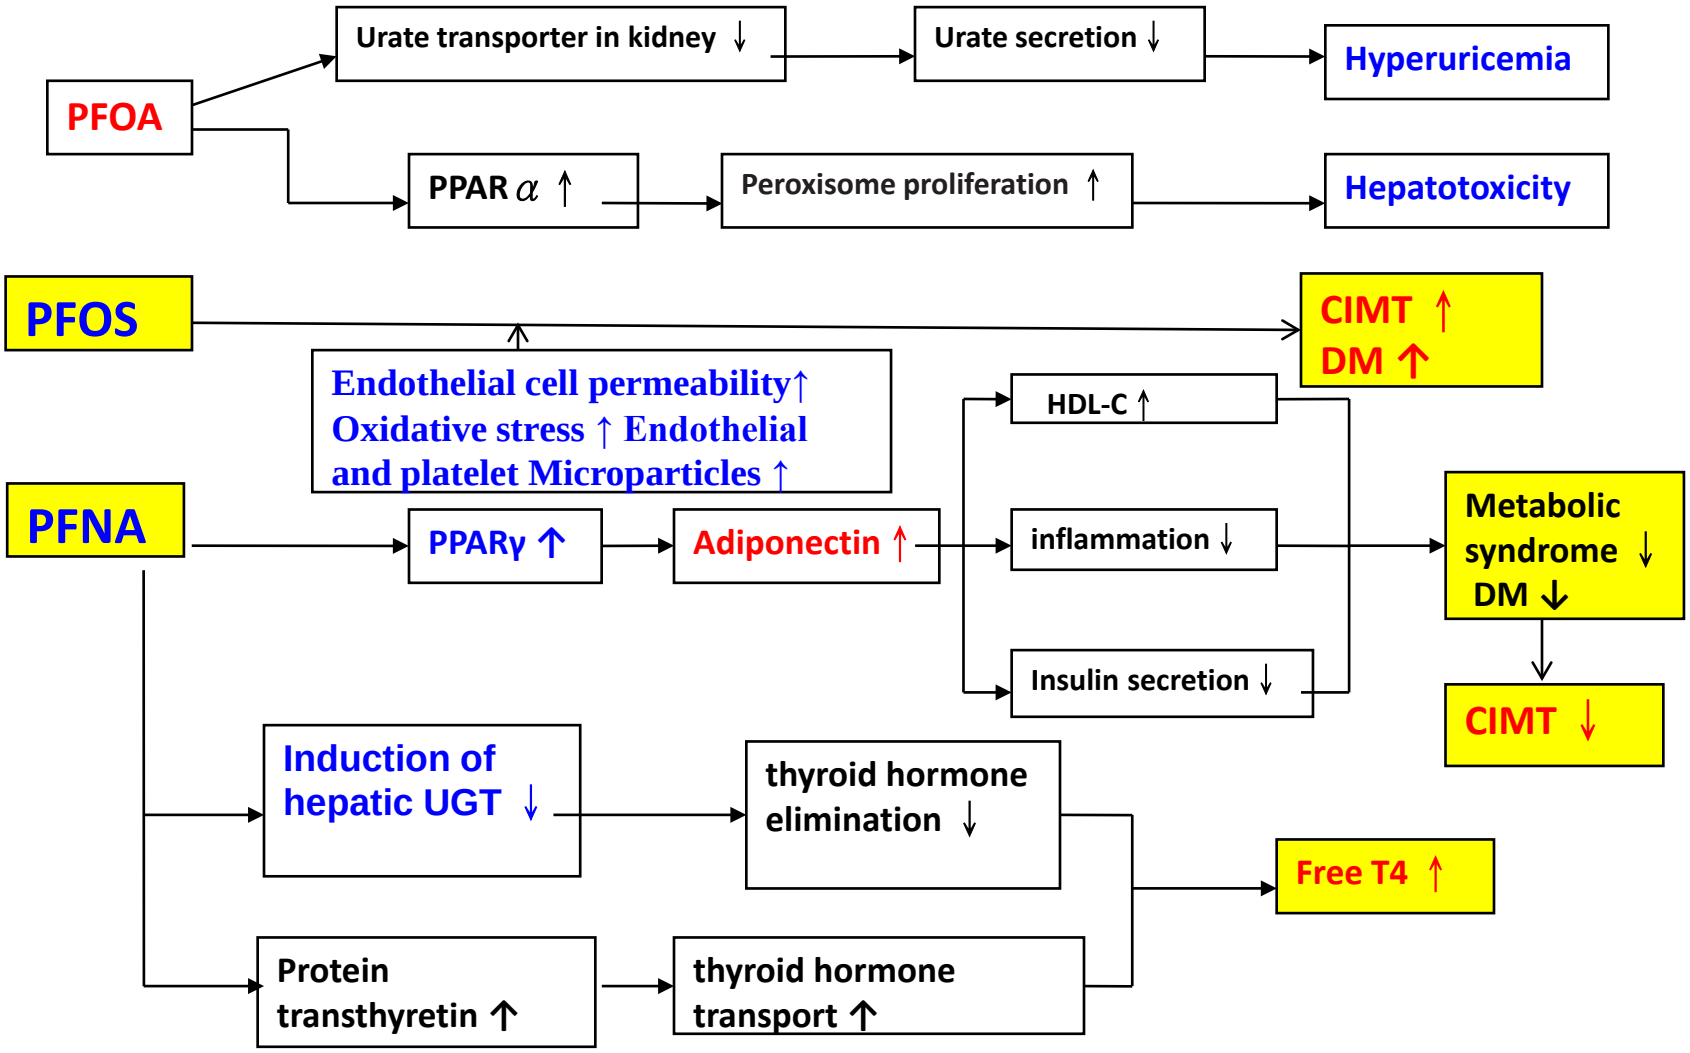
Proposed Mechanism of PFCs on Health



Conclusions

- Plasticizers and PFCs are common pollutants around us.
- **The diabetogenic and atherogenic potentials of DEHP and PFOS was demonstrated in our series of studies.**
- How to prevent exposure to DEHP and PFOS in our daily life and dietary habits are very important for primary prevention of diabetes and cardiovascular disease.
